ZIP SHA-256	5e303b70987d99728639dc8edfa2480cb7eca486d631b2e95abf1147e4bd90df
Manifest SHA-256	712d4b86f10c1c65d36dda183aa55300d25856b7446a486fbd50ae0dc450ef19

READING NOTES

Each file starts on a new page and has a PDF bookmark.

Every listing includes repository-relative path, byte count, line count, and SHA-256.

Long logical lines are wrapped at 176 characters; continuation rows use a > marker.

Tabs are rendered as four spaces. Non-printing controls are rendered as explicit escape sequences.

The companion ZIP remains the byte-exact, machine-consumable source archive.

```

```

1 | """Phase 14C `.gate`: package a driven worktree as a CANDIDATE + controlled merge.
2 |
3 | This is the FINAL cell of directive $9 table 14C:
4 |
5 |     ... isolated worktree modification → CANDIDATE artifact submitted → controlled merge path passed
6 |
7 | `.harness` proved a supervisor-spawned OpenCode; `.worktree` drove it in an isolated worktree from
8 | scoped MCP context. This module turns a driven `NodeWorktree` into a governed CANDIDATE published to
9 | shared MCP memory THROUGH the node-local gate, and couples that gate verdict to
10 | `node_runtime.workspace.worktree.MergeCoordinator` so the trunk merge requires the SAME passing gate
11 | AND explicit operator approval. Load-bearing invariants, all enforced in code and fail-closed:
12 |
13 | - **Worker publishes CANDIDATE, never self-canonizes (invariant 10).** `publish_candidate` writes
14 |   the entry with `status="CANDIDATE"`; promotion to ACCEPTED is a SEPARATE transition performed by a
15 |   DIFFERENT node (invariant 18) – never by this module.
16 | - **Provenance on every shared entry (invariant 11).** Every CANDIDATE carries the full
17 |   `memory@1.0` provenance block (author_node/task_id/ts/directive_version/confidence + evidence).
18 | - **A failed artifact cannot advance (invariant 16).** The node-local gate runs BEFORE publish; a
19 |   FAIL verdict refuses to publish AND refuses to merge – nothing leaves the node.
20 | - **The system never self-authorizes the protected merge (invariant 1).** The trunk merge goes
21 |   only through `MergeCoordinator.merge`, which requires the passing gate verdict AND
22 |   `operator_approved` is True; a refusal is a governed outcome, recorded, never a crash.
23 |
24 | HONESTY (directive $6, register U31). A small local coder did NOT complete a live schema-correct edit
25 | this session (`.worktree` recorded this: OpenCode drove and executed its real tools, but the flaky
26 | local model did not land a completed edit headlessly). So the worktree edit this module packages and
27 | merges is a DETERMINISTIC SEEDED edit, not live-model output – `CandidatePacket.from_live_model`
28 | records which, and the caller/evidence states it plainly. The GOVERNED path (package → node-local
29 | gate → CANDIDATE publish → controlled merge) is the system under test and is exercised end-to-end
30 | regardless of where the bytes came from; no live landed edit or live merge is ever claimed here.

1 | """Drive OpenCode for real in an isolated worktree, from scoped MCP context. Phase 14C `.worktree`.
2 |
3 | The chain this module proves (directive $9 table 14C, middle cell):
4 |
5 |     scoped MCP context → isolated worktree modification → tests run
6 |
7 | The CANDIDATE artifact submission + controlled merge is the NEXT sub-step (`.gate`); this one stops
8 | at "the worktree has been driven and its tests have run".
9 |
10 | `OpenCodeDriver` is deterministic ORCHESTRATION around a real `opencode run` subprocess. The
11 | subprocess call is injected as a `Runner`, so the deterministic suite proves every governance
12 | property with a scripted fake while the live integration test passes the real subprocess runner –
13 | the same mock-first/real-live split the frontier (`claude_code.py`) and `.harness` layers use.
14 |
15 | Load-bearing properties, all enforced in code and fail-closed (Buildout Directive $4):
16 |
17 | - **Scoped context, never the full transcript (invariant 8).** `read_scoped_objective` fetches
18 |   EXACTLY the one assigned MCP entry (`get_content` by entry_id). The driver never sweeps the
19 |   store, never blanket-forwards the conversation.
20 |
21 | - **Isolated worktree modification (Phase 10; invariants 29, 1).** OpenCode is pinned to the
22 |   node's OWN git worktree via `--dir <worktree>` + `cwd`. Changes are read back with `git status`
23 |   INSIDE the worktree; the base trunk working tree is checked for any modification outside the
24 |   worktree – a change there flips `escaped=True` and is logged (and if the check itself cannot
25 |   run, `escaped` is forced True, `containment_verified=False` – fail closed, never read as
26 |   "clean"). Honesty per U10: this detects escapes into the BASE-TRUNK working tree only; it is a
27 |   *detected* escape via worktree scoping + a git-status diff, NOT an OS syscall sandbox around a
28 |   rogue subprocess (a write elsewhere on disk is out of scope here). The node's own
29 |   `WorkspaceBinding` path guard governs the DRIVER's filesystem calls (and worktree.py's commit
30 |   path); it is NOT applied to the spawned `opencode` subprocess.
31 |
32 | - **U30 discharged – OpenCode config isolation.** OpenCode reads provider config from
33 |   `opencode.json`/`OPENCODE_CONFIG`, not only the env. `write_scoped_opencode_config` writes a
34 |   SESSION-LOCAL config declaring ONLY the loopback Ollama provider + the pinned local model, and
35 |   the driver points `OPENCODE_CONFIG` at it – so a host cloud-provider `opencode.json` cannot
36 |   influence the driven run. Defence in depth: the harness `build_env` scrubs every provider
37 |   credential var and the model is pinned to `ollama/*` (`_require_local_model`), so even a leaked
38 |   cloud provider definition has no key and is never selected. The config's Ollama `baseURL` MUST
39 |   be loopback or the write is refused ($2.3 – no off-box/paid routing).
40 |
41 | - **$2.2 no credential / $2.3 local-only.** Inherited verbatim from the harness builders.
42 |
43 | HONESTY (recorded, directive $6). OpenCode ITSELF is genuinely driven headlessly: it spawns,
44 | connects to the pinned local Ollama model, runs its agent loop, and EXECUTES its real tools
45 | (read/glob/edit) inside the worktree – observed live. Small local coder models are FLAKY at
46 | COMPLETING a multi-step tool edit headlessly (tool-arg schema slips, early stops, prose-only turns)
47 | – a model-quality limitation, not a harness/governance defect (model-quality conclusions are
48 | limited to local backends, $5 phase-13). The live test therefore asserts the drive + real tool
49 | execution + worktree confinement and RECORDS whether a completed edit landed; it never fabricates
50 | an edit that the model did not produce.

1  """First LIVE local coding harness – OpenCode (Phase 14C `harness`).
2
3  Phase 6 stood up a `coding_node` roster entry but recorded (spec-audit F1) that it was a
4  *direct* local coder (single-shot Ollama `generate`), NOT a driven coding-TUI harness, and so
5  advertised **no** `harness_class`. Phase 14C closes exactly that gap: it proves OpenCode
6  *itself* is driven as a first-class coding harness (invariant 23 – coding harnesses
7  interchangeable behind one contract), spawned by the Node Runtime supervisor.
8
9  This module is the OpenCode side of that contract. It is deliberately small and, like the
10 frontier backend (`adapters/frontier/claude_code.py`), splits into:
11 - `MockOpenCodeHarness` – deterministic, spawns nothing; the mock-first proof of the whole
12 supervised/gated path uses it.
13 - `OpenCodeCliHarness` – the REAL harness that invokes the host's `opencode` CLI. Its
14 `version()` spawns `opencode --version` (a benign, local, credential-free probe); its
15 `build_run_command`/`build_env` are pure and separately testable so the two load-bearing
16 safety properties are proven WITHOUT a heavy drive:
17 * **$2.2 – no credential handling.** `build_env` scrubs every provider credential/API-key
18 var from the child environment, so a driven OpenCode session cannot transmit a secret.
19 * **$2.3 – no paid services.** The sovereignty guarantee is ENFORCED, not conventional:
20 `build_run_command` fail-closed refuses any model that is not a local `ollama/*` ref
21 (`ModelNotLocal`), and `build_env` scrubs every cloud provider key AND drops a non-loopback
22 `OLLAMA_HOST` (which would route the "local" model to a remote/paid endpoint). With no
23 reachable cloud key and a loopback-pinned local model, the local Ollama daemon is the only
24 model path left.
25
26 OpenCode + Ollama are LOCAL (no subscription, no credential), so – unlike the frontier path –
27 this harness is NOT subject to `LIVE_OPERATION_AUTHORIZED` (that gate is frontier-only,
28 directive $10.1) and NOT counted by the `SubscriptionGovernor` (local terminals are never
29 subscription-bounded; see subscription_governor.py). $10.2 authorized downloading the OpenCode
30 binary + Ollama coder pulls; on this host both are already present, so NO download is performed
31 this session (recorded in evidence). The supervised spawn gate + presence/version gate live in
32 node_runtime/supervisor/opencode_spawn.py.
33
34 The actual code-editing drive (scoped MCP context → isolated worktree edit → tests → CANDIDATE
35 → controlled merge) is the `worktree`/`.gate` sub-steps; this `harness` sub-step delivers the
36 harness contract, the presence/version gate, and the supervised spawn.

2
3  The conductor is an INTERFACE; the current runtime selection (today: fable-5) backs it but
4  the architecture knows only this contract (I-CN1). This adapter:
5  - loads the 12 operator-authored conductor files FROM MCP, in declared order, BEFORE it
6  produces or assigns any work (Plan §2.10.4; the conductor-file draft mandates this);
7  - runs the conductor loop against a backend (Phase 4: the deterministic mock reasoner);
8  - holds NO provider/subscription credential (Phase 4 exit criterion) – it carries only an
9  MCP identity reference; the model backend credential, if any, stays host-side;
10 - is subscription-governed (I-X3): one terminal per subscription, acquired at start and
11 released on close / before succession.
12 Phase 4 records conductor DECISIONS as CANDIDATE proposals (the conductor may propose, not
13 promote – invariant 16/§4.5); launching and assigning workers is Phase 5.

1  """Gemini · Antigravity (`agy`) – headless worker adapter. Phase 18B `.adapter`, register OP-12.
2
3  The second of the two providers the operator authorized at OP-12 (directive §17), on the
4  operator's Google AI Pro subscription. Same shape as its sibling `grok_build`: a headless
5  reasoning worker behind the SAME governed `ModelWorkerAdapter` contract, sharing one argv/env
6  policy (`provider_cli_common`) so the two providers cannot drift apart. No parallel registry, no
7  second control path (operator directive §8).
8
9  **Never the retired CLI.** Operator directive §4.2/§14 forbids falling back to the personal-account
10 Gemini CLI, and `node@1.0`'s `gemini_cli` enum member names exactly that retired tool – so this
11 adapter does not borrow it as a vocabulary shortcut. The id is the operator's own OP-12 product-layer
12 id, and the display name is "Gemini · Antigravity" everywhere an operator can read it.
13
14 **The boundary this module sat behind, and where it moved (U227 → OP-12.1).** Through 18B/18C
15 `node@1.0`'s `adapter` enum had no member for `google_antigravity`, the enum is frozen and the
16 amendment was operator-reserved, so `NodeRegistry.register` refused. **The operator ruled on
17 2026-08-01 (OP-12.1, directive §17.1): by SUCCESSOR SCHEMA** – `schemas/node.schema@1.1.json`
18 beside the untouched `@1.0` – and a Sovereign node record can now name this provider. Note what
19 the successor did NOT do: it did not touch `gemini_cli`, whose meaning is still the retired
20 personal-account CLI above, and it did not authorize a live call, which still needs the operator's
21 switch, the terms determination and an I-X3 lease on `google_antigravity_subscription`
22 (allowance 1).
23
24 **Credential posture (§13 / build directive §2.2).** The adapter invokes the host's
25 already-authenticated `agy` CLI, which keeps its Google OAuth in its own host-native store. This
26 code never reads, stores, prints, or transmits it; the child environment is scrubbed of every key-
27 and endpoint-bearing variable, `GEMINI_API_KEY` / `GOOGLE_API_KEY` included.
28
29 **Command surface (§2 – the installed CLI is authoritative).** Read off this host's captured
30 `agy --help` (2026-07-31): `-p/--print`, `--output-format` (`text | json | stream-json`),
31 `--model`, `--mode` (`accept-edits, plan`), `--add-dir`. Recorded deltas: `agy` has **no `--cwd`
32 flag**, so the workspace is bound by the child's working directory plus `--add-dir`; and the
33 directive's §10 spelling `stream-json` is confirmed present, though this sub-step's one-shot
34 headless mode uses `json`.
35
36 **`--sandbox` is deliberately not emitted.** The flag exists, but its entire documented meaning is
37 "Run in a sandbox with terminal restrictions enabled" – which does not say what is restricted. 18A
38 recorded that an unverified containment claim is worse than none, and that holds here: enabling a
39 flag whose behaviour this build cannot describe would put an unfalsifiable safety claim into the
40 evidence. Revisited on live evidence at 18C (U261), never on a guess.

118         operator directive §9).
119
120         Distinct from `AntigravityCliBackend.build_command` (the one-shot `-p ... --output-format json`
121         worker). No `--p`/`--print`, no `--output-format`, and no `--prompt-interactive`: bare `agy` with
122         flags opens the session the operator types into. `--prompt-interactive` is omitted for the same
123         reason grok's positional `[PROMPT]` is – an initial prompt would be this build speaking in a
124         session the operator owns.
125
126         Pinned, each for a reason (§11 / T2 – agy reads project config and rules files the node's own
127         tree may contain):
128         * `--mode plan` – the narrower of this CLI's own two values (`accept-edits, plan`), the same
129         one the headless path pins, so a config default cannot supply the permissive one. Never
130         `--dangerously-skip-permissions`: the shared guard refuses it;
131         * `--add-dir <workspace>` – this CLI has NO `--cwd`, so the workspace binding is two facts:
132         the child's working directory (the launch ticket's `cwd`, which the shell's ConPTY spawn
133         applies) and this explicit statement of it to the agent. Emitting `--add-dir` without the
134         ticket's `cwd` would be a claim about a binding only half made;
135         * `--model <slug>` when one was selected; `None` CLI default, RECORDED as a fallback.
136

1  """First LIVE frontier adapter – Claude Code (Anthropic first-party CLI). Phase 14B `.adapter`.
2
3  The one provider the operator authorized a live path for (register OP-4/OP-5, directive
4  §10.1). This module supplies the *backend* that plugs into the existing, already-governed
5  `ModelWorkerAdapter` contract (adapters/model_adapter.py): scoped context in from MCP, the
6  node-local gate before publish, a CANDIDATE artifact out with provenance. The backend is the
7  only new surface; the governance path is unchanged and reused verbatim.
8
9  Non-negotiables encoded here (directive §2.2 / §10.1; Plan §18.3–18.4):
10 - **No credential handling, ever.** The adapter invokes the host's already-authenticated
11   `claude` CLI, which holds its OAuth subscription token in a host-native store (a file/
12   keychain the CLI manages, NOT an environment variable). This code NEVER reads, extracts,
13   stores, or transmits that credential. As defence-in-depth the child environment is also
14   scrubbed of every credential- or endpoint-bearing variable (any `ANTHROPIC_*`, `AWS_*`,
15   `GOOGLE_*`, `CLAUDE_CODE_*`, or `*TOKEN*/`*SECRET*/`*API_KEY*` name – see
16   `_is_credential_key`) so no key can be transmitted and no endpoint override can redirect
17   the call: the *subscription* OAuth path via the host-native store is the only one left. If
18   the operator's only auth were an in-env token, scrubbing it forces a fail-closed auth pause
19   (transmitting it would violate §2.2) – the operator re-logs in via the CLI's own store.
20 - **Mock-first.** `MockClaudeCliBackend` is deterministic and spawns nothing; the whole
21   governed path is proven with it. `ClaudeCliBackend` (the real subprocess) is NEVER used
22   by the deterministic test suite – only by the opt-in, operator-gated live smoke, exactly
23   like `OllamaBackend`.
24 - **Fail-closed on auth.** An expired/failed subscription surfaces as `ClaudeCodeAuthError`
25   – the supervisor pauses the node (Plan §18.4); there is NO silent API-key fallback.
26
27 Live-spawn governance (LIVE_OPERATION_AUTHORIZED, I-X3, R8 operator terms, CLI presence)
28 lives in node_runtime/supervisor/frontier_spawn.py – the real supervisor/startup path.

222 |
223 |     Phase 15B `.gate` (spec-audit owed item): a per-node decision must record the model the CLI
224 |     *actually ran*, read back from its own JSON response – NOT the requested `--model` slug, which
225 |     is only an unverified label until a live call confirms it (directive §11 15B honesty).
226 |
227 |     RECONCILED AGAINST THE REAL SHAPE (Phase 15D `.flow` LIVE re-run, OP-9 – the operator-gated
228 |     live smoke the earlier drafts deferred to). The captured `claude -p --output-format json`
229 |     envelope (`tools/live/claude_json_shape.captured.json`) carries NO top-level `model` string;
230 |     the executing checkpoint lives in `modelUsage`, a map of `model_id -> {..., costUSD, ...}`, and
231 |     on a real call it holds MORE THAN ONE key – the primary conductor model plus the CLI's own
232 |     auxiliary fast-model helper (e.g. `claude-haiku-4-5-*`). Resolution, all deterministic and fail
233 |     closed (a checkpoint id is NEVER guessed):
234 |
235 |     * a top-level string `model` wins if present (some builds / future shapes);
236 |     * a single-key `modelUsage` is unambiguous – that key is the model;
237 |     * a MULTI-key `modelUsage` is reconciled to the COST-DOMINANT model: the entry with the
238 |       strictly-greatest numeric `costUSD`, the CLI's own integrated measure of which checkpoint
239 |       did the work (the primary always dwarfs the fast-model helper in billed cost). A TIE, a
240 |       missing/non-numeric `costUSD` on any entry, a non-dict entry, or a non-string/blank key
241 |       `None` (ambiguous unverified, never a coin-flip between two real checkpoints).
242 |
243 |     STATED LIMIT (U57): cost-dominance is a reconciliation, not a field the CLI labels "primary".
244 |     It is correct for the observed shape (a primary model + a cheaper helper) and fails closed when
245 |     it cannot tell; a hypothetical future config in which a helper outspends the primary would be
246 |     misattributed. The full `modelUsage` key set is surfaced by callers (never hidden) so the
247 |     reconciliation is auditable.""

569 |     """The verification record backing a `live` claim, or None. FOUR conditions, ALL required:
570 |
571 |     1. the backend IS (or directly wraps) the exact vendor CLI class – not a subclass, not a duck;
572 |     2. a call was SPENT since `calls_before` (an unreadable counter fails closed to "spent", since
573 |        under-reporting spend is the dishonest direction);
574 |     3. it carries a non-blank checkpoint STRING that its own `generate` read back out of the CLI's
575 |        JSON response (`extract_reported_model`) – a requested `--model` slug never reaches it;
576 |     4. that checkpoint is datable to a call made AFTER `calls_before`. `reported_model` is never
577 |        cleared and `calls` is a LIFETIME counter, so without (4) a backend reused from an earlier
578 |        run – every call in THIS one having failed – still presents a verified checkpoint for a run
579 |        in which nothing succeeded.
580 |
581 |     `calls_before=None` means "no snapshot was taken", which cannot satisfy (4) and therefore
582 |     cannot yield a record. Fail closed: the absence of evidence is not evidence. Because of that,
583 |     condition (2) is evaluated only against a real snapshot – there is no "any call at all" fallback
584 |     here, and an UNREADABLE counter fails CLOSED (no verification), not open. That is the opposite
585 |     of the leg vocabulary's treatment of an unreadable counter, deliberately: for reporting SPEND,
586 |     over-reporting is the honest direction, but for verifying a LIVE claim, under-claiming is.
587 |
588 |     STATED LIMIT (U43): these are instrumentation attributes on an object the CALLER supplies, and
589 |     exact-type checking constrains its class, not its behaviour. Forging both stamps on a genuine
590 |     backend, reassigning `__class__`, or replacing `generate` on a genuine instance all still pass.
591 |     What this rules out is every ACCIDENTAL and every mock-SHAPED path. `live` is trustworthy
592 |     exactly as far as the caller is.
593 |     """

1 | """Live model-availability PROBE for the `claude` CLI – Phase 17A `.roundtrip`.
2 |
3 | **The defect this closes.** Phase 17A `.pty` made the shell run the real interactive `claude` session
4 | in pane 1's ConPTY with the operator's conductor selection as its `--model` slug (`fable-5`). The
5 | session was born, supervised, counted and bound – and every prompt typed into it came back with
6 |
7 |     There's an issue with the selected model (fable-5). It may not exist or you may not have
8 |     access to it. Run /model to pick a different model.
9 |
10 | A live session that cannot answer is the black pane with extra steps. The whole build has said, since
11 | Phase 15B, that an operator model LABEL is *not* a CLI slug and that the accepted id "is only
12 | confirmed by a live smoke" – with `bind_conductor_selection(model_available=...)` already wired for
13 | "the live probe that the first live smoke supplies". This module is that probe.
14 |
15 | **What it establishes, and what it refuses to.** A slug is ACCEPTED only when the host CLI ran a real
16 | one-shot call on it. Three things are deliberately NOT evidence:
17 |
18 | * a 0 exit – the CLI delivers "no such model" as an ordinary assistant reply, so the reply TEXT is
19 |   checked against the CLI's own wording as well as the error path;
20 | * an auth/rate/usage-limit condition – it says nothing about the slug, so the probe stops and
21 |   records INCONCLUSIVE rather than demoting the operator's selection on unrelated evidence;
22 | * a backend that is not the exact vendor CLI class – a mock spends no subscription call and can
23 |   never mint an accepted slug (the same `is_live_cli_backend` rule the rest of the build uses).
24 |
25 | **Candidates are derived, never invented.** For a label the vendor's own id namespace supplies one
26 | alternative spelling: `claude-<label>` (the CLI's release notes name its ids that way – e.g.
27 | `claude-opus-5`). Both forms are *candidates*; only a successful call promotes one. Exhausting them
28 | with model-unavailable answers is the CLI-DEFAULT FALLBACK – recorded and surfaced in the ticket,
29 | the chrome and the receipt, never silent (directive §11 15B / §16 17A).
30 |
31 | **Fail-closed direction for a CACHE.** The record is a cache of a live observation, so an unreadable
32 | or shape-drifted ledger reads as *unprobed* (carry the label verbatim, exactly as before this
33 | module existed) – never as *unavailable*, which would silently strip the operator's selection.
34 |
35 | Pure except for `probe_claude_model`'s injected `backend_factory`: the live call is the caller's, so
36 | every rule here is tested with zero live calls.

1  """OpenAI Codex CLI – detection / probe surface. Phase 15C `.detect`.
2
3  The second live frontier provider the operator authorized (register **OP-6**, directive $11
4  track 15C; $12 OP-7 revised order 15A+15C). This module is the `.detect` sub-step ONLY: it
5  proves the host `codex` CLI is present, at a parseable version, and authenticated – and it
6  records what the CLI structurally accepts for per-node model selection. It makes **no live
7  model call** (`codex exec` is never invoked here): every probe is a benign, local, credential-
8  free metadata call (`codex --version`, `codex login status`, `codex exec --help`).
9
10 Deliberately NOT here (owed to `.adapter` / `.gate`, kept honest):
11 - the live `CodexCliBackend` behind the governed `ModelWorkerAdapter` contract;
12 - the fail-closed supervised spawn path (mirrors node_runtime/supervisor/frontier_spawn.py:
13   assert_startup + assert_provider_live('openai_codex_cli') + [OPERATOR] live-terms + CLI
14   presence + I-X3 governor at allowance=live_auth.terminals_per_subscription);
15 - the env-scrub SUPERSET applied to the child of `codex exec` (OPENAI_*/key families) and the
16   node-controlled-untrusted `AGENTS.md`/`~/codex` config pin (T2, like OpenCode's U30);
17 - the one live smoke per available model.
18
19 Non-negotiables already binding at detection (directive $2.2):
20 - **No credential handling, ever.** `codex login status` reports auth *state* ("Logged in
21   using ChatGPT") – it does not expose the OAuth token. This module NEVER reads `~/codex/
22   auth.json`, NEVER uses `--with-api-key`/`--with-access-token`, and NEVER stores/transmits a
23   credential. The token stays in the CLI's own host-native store.
24
25 Model-id honesty (directive $11 15C – "probe accepted model IDs ... record what the CLI really
26 accepts, unavailable recorded fallback surfaced in the roster, never silent"):
27   The Codex CLI's `-m/--model` accepts an arbitrary slug that is validated only at `codex exec`
28   time; there is **no offline `models list` subcommand**. So the specific accepted ids for the
29   operator-named GPT-5.5 line ("5.5", "5.5 Sol") CANNOT be confirmed without a live call. This
30   module therefore records them as *unverified candidates* (`verified=False`) plus the
31   structural fact that the `-m/--model` selector exists; the accepted-id resolution (and any
32   recorded fallback) is a `.adapter`/`.gate` live smoke – never fabricated here.

317 | # =====
318 | # Phase 15C `adapter` – the LIVE Codex backend behind the governed ModelWorkerAdapter contract.
319 | #
320 | # Mirrors adapters/frontier/claude_code.py exactly: the backend is the only new surface; the
321 | # governance path (scoped MCP context in → node-local gate → CANDIDATE out with provenance) is
322 | # the shared, already-governed ModelWorkerAdapter, reused verbatim. The fail-closed supervised
323 | # spawn (LIVE_OPERATION_AUTHORIZED / I-X3 / R8 operator-terms / CLI presence) lives in the real
324 | # startup path node_runtime/supervisor/codex_spawn.py – never here.
325 | #
326 | # Non-negotiables encoded here (directive §2.2 / §11 track 15C; Plan §18.3–18.4):
327 | # - **No credential handling, ever.** The adapter invokes the host's already-authenticated
328 | #   `codex` CLI, which holds its ChatGPT-subscription OAuth token in a host-native store
329 | #   (`~/codex/auth.json`, managed by the CLI – NOT an environment variable). This code NEVER
330 | #   reads that file, NEVER passes `--with-api-key`/`--with-access-token`, and NEVER stores or
331 | #   transmits a credential. As defence-in-depth the child env is scrubbed of every credential/
332 | #   endpoint var (OpenAI/Azure/other key families + a bare KEY/AUTH/TOKEN/SECRET/CREDENTIAL
333 | #   superset – see `_is_credential_key`), so no key can be transmitted and no endpoint override
334 | #   can redirect the call: the subscription OAuth path via the CLI's own store is the only one
335 | #   left.
336 | # - **T2 – node-controlled config is untrusted (like OpenCode's U30).** `codex exec` reads
337 | #   `AGENTS.md` from the working tree and `~/codex/config.toml` (host-global). Containment is
338 | #   pinned by CLI flags that take precedence over config: an explicit `--sandbox` (read-only for
339 | #   reasoning, workspace-write for coding – NEVER `danger-full-access`), an explicit model, and
340 | #   `--cd` scoping a coding run to the node's OWN isolated worktree (Phase 10). The dangerous

```

```

341 # bypass flags are refused structurally (`_FORBIDDEN_CODEX_ARGS`). Residual host-`config.toml`
342 # keys the flags do not override (e.g. declared MCP servers/hooks) are a recorded live-run item
343 # (U32) – the CODEX_HOME auth dir is deliberately NOT relocated, because that would sever the
344 # host OAuth the $2.2 path depends on (relocating it and copying auth.json would BE credential
345 # handling).
346 # - **Mock-first.** `MockCodexCliBackend` is deterministic and spawns nothing; the whole governed
347 # path is proven with it. `CodexCliBackend` (the real subprocess) is NEVER used by the
348 # deterministic suite – only by the opt-in, operator-gated live smoke.
349 # - **Fail-closed on auth.** An expired/failed subscription surfaces as `CodexAuthError` – the
350 # supervisor pauses the node (Plan §18.4); there is NO silent API-key fallback.

464     (Phase 17B `ticket`; OP-7 §12.3 attended/autonomous). Distinct from `CodexCliBackend.build_command`,
465     which is the one-shot `codex exec ... <prompt>` headless worker mode.
466
467     NO `exec` subcommand and NO prompt argument: the CLI opens its interactive surface. The governed
468     facts the headless path pins are pinned identically here – an explicit `-m` (per-node model,
469     unverified until a live smoke), an explicit `--sandbox` (never `danger-full-access`), and `--cd`
470     scoping the session to the workspace it was authorized for – because a node-controlled
471     `~/codex/config.toml` must never be able to widen either (T2 containment). `workspace-write`
472     without a `--cd` scope is refused, exactly as the exec path refuses it (Phase 10 / T2).
473
474     Pure and deterministic: it builds argv only. The ConPTY spawn and the host-native OAuth
475     credential stay entirely outside this function (the credential is never read/stored/transmitted).
476     """

1  """Grok Build (`grok`) – headless worker adapter. Phase 18B `.adapter`, register OP-12.
2
3  The first of the two providers the operator authorized at OP-12 (directive §17). This module is
4  the `.adapter` sub-step: a headless reasoning worker behind the SAME governed contract every other
5  model node in this build uses – `ModelWorkerAdapter`, which reads scoped context from MCP, runs
6  the node-local gate, and publishes CANDIDATE with provenance. The backend is the only new surface.
7  There is no parallel registry and no second control path (operator directive §8).
8
9  Deliberately NOT here, and owed to the sub-steps that follow:
10 * the picker option and the launch ticket (`.picker`, since done – that sub-step also added
11   `build_interactive_grok_command` BELOW, the argv for the supervised ConPTY pane, because the
12   interactive argv is this provider's own knowledge and belongs beside its headless twin);
13 * the I-X3 governor lease on `grok_build_subscription` (allowance 1, never merged with the
14   Antigravity subscription – operator directive §12);
15 * any live call at all (`.18C`, and only behind the operator's own `config/live_operation.json`).
16
17 **The boundary this module sat behind, and where it moved (U227 → OP-12.1).** Through 18B/18C:
18 `node@1.0`'s `adapter` enum had no member for `grok_build`, the enum is frozen at Phase 0 and
19 pinned by Architecture Plan §9.1, and the amendment was operator-reserved – so `NodeRegistry.
20 register` refused, and `gate/phase-18b` deliberately did not close on "U227 is answered". **The
21 operator ruled on 2026-08-01 (OP-12.1, directive §17.1): by SUCCESSOR SCHEMA.**
22 `schemas/node.schema@1.1.json` sits beside the still-untouched `@1.0` and admits `grok_build`, so
23 a Sovereign node record CAN now name this provider. Two things did not change with it: the frozen
24 `@1.0` file and Plan §9.1 are exactly as they were, and admitting the vocabulary admits nothing
25 else – a live call still needs the operator's `config/live_operation.json`, the OP-9-class terms
26 determination, and an I-X3 lease on `grok_build_subscription` (allowance 1).
27
28 **Credential posture (§13 / build directive §2.2).** The adapter invokes the host's
29 already-authenticated `grok` CLI, which keeps its xAI OAuth in its own host-native store. This
30 code never reads, stores, prints, or transmits that credential; there is no API-key path at all,
31 and the child environment is scrubbed of every key- and endpoint-bearing variable
32 (`.provider_cli_common.scrub_provider_env`) so none could be transmitted even by accident.
33
34 **Command surface (§2 – the installed CLI is authoritative).** Every flag below was read off this
35 host's captured `grok --help` (2026-07-31, `docs/evidence/live/phase18a_host_recon.json`):
36 `--p/--single` (single-turn headless prompt), `--output-format json`, `--cwd`, `--permission-mode`,
37 `--no-memory`, `--m/--model`. Recorded deltas: the operator directive's §10 example carried
38 `--no-auto-update`, which **this build of `grok` does not have** – omitted, not silently
39 substituted; and §10 preferred `--output-format streaming-json` "for live pane updates", which this
40 sub-step does not use because a one-shot headless worker consumes a single final answer. The
41 streaming spelling is confirmed present and is the `.picker` sub-step's to use for a live pane. `grok
42 agent stdio` (ACP) is not used: directive §10 permits it only if a fitting JSON-RPC/ACP client
43 already exists in this repository, and none does, so building one would be a new general framework
44 the directive tells us not to write – recorded as **U262**, because "we did not use the transport
45 the directive mentioned" is a decision an auditor should find written down rather than infer from
46 absence.

80 GROK_OUTPUT_FORMAT = "json" # 'plain | json | streaming-json | streaming-messages-json'
81 GROK_PERMISSION_MODE_FLAG = "--permission-mode"
82 # '--no-memory' ("Disable cross-session memory for this session") is emitted because the capture
83 # documents it on the surface this build uses and cross-session memory is a blanket-context vector:
84 # a node's prior conversations would enter this one without passing the scoped-context compiler
85 # (invariants 8/9). Narrowing, node-controlled by default, pinnable here – so it is pinned.
86 GROK_NO_MEMORY_FLAG = "--no-memory"
87 # Pinned so a node-controlled `~/grok/config.toml` cannot supply a permissive default instead
88 # (§11). `plan` is a REASONED choice, not a documented ranking: the CLI's enum (default,
89 # acceptEdits, auto, dontAsk, bypassPermissions, plan) is not ordered by its help, and calling it
90 # "the most restrictive value" would be an inference stated as evidence. What is enforced is
91 # narrower: none of the auto-approving values can be emitted at all (`FORBIDDEN_PERMISSION_MODES`).
92 #
93 # MEASURED AND LEFT ALONE (18E `live.shape`, 2026-08-02, U310). Grok's single-turn `-p` run
94 # returns `{"text": "", "stopReason": "cancelled", ...}` on this host – the CLI says nothing – and
95 # the first reading of that was that `plan` had no approval channel to hand a plan to. A second
96 # governed live probe with `--permission-mode default` was run to test exactly that, and it
97 # CANCELLED IDENTICALLY. The mode is not the cause, so the pin does not move: changing it would
98 # have been a widening bought with a refuted hypothesis. The real cause is open (U310).
99 #
100 # RE-EXAMINED AND RESTORED at Phase 19 unit 1 (U327 settled, D-P19-1). The untagged post-18E range
101 # moved this to `default` and DELETED the paragraph above; the loop re-read the two live receipts
102 # it cites (`docs/evidence/live/phase18e_probe_document_shape_20260802T0219Z.json`, `plan`,
103 # `accepted: false`; `..._grok_default_mode_20260802T0224Z.json`, `default`, `accepted: false`) and
104 # they still say what they said – the widening buys no measured behaviour. `--no-plan`, which the
105 # same range emitted beside `default` and removed from `FORBIDDEN_PROVIDER_ARGS`, is gone with it:
106 # the installed capture reads "Disable plan mode", so it is this pin's cancellation under another
107 # name. If a live run ever shows plan mode blocking a governed worker, that is a MEASUREMENT and
108 # the basis for an amendment – it is not an assumption this build gets to make in advance.

161 |     """Argv for an INTERACTIVE `grok` TUI session in a supervised pane (188 `.picker`;
162 |     operator directive §9).
163 |
164 |     Distinct from `GrokCliBackend.build_command`, which is the one-shot headless worker
165 |     (`-p ... --output-format json`). Here there is NO `-p`, NO `--output-format` and NO positional
166 |     PROMPT: `grok [OPTIONS]` with no prompt argument opens the TUI the operator types into, which is
167 |     what §9 asks for. The captured usage line – `grok [OPTIONS] [PROMPT] [COMMAND]` – is the
168 |     authority for that shape, and the omitted `[PROMPT]` is deliberate: an initial prompt would be
169 |     this build putting words in a session the operator owns.
170 |
171 |     What IS pinned, and why each one (§11 – provider tool permission is subordinate to the launch
172 |     ticket, and T2 – `~/grok/config.toml` is node-controlled untrusted input):
173 |     * `--cwd <workspace>` – the governed workspace binding the ticket authorized;
174 |     * `--permission-mode plan` – the same value the headless path pins, so a config default
175 |     cannot supply an auto-approving one. Never `--always-approve`/`bypassPermissions`: the
176 |     shared guard refuses them, and this session gets no wider authority than the headless one.
177 |     `--no-plan` is not emitted and is forbidden again (U327, 19.1): "Disable plan mode" would
178 |     cancel this pin, and cancelling a pin silently is what the operator ruled against;
179 |     * `--no-memory` – cross-session memory would carry a prior conversation into this one without
180 |     passing the scoped-context compiler (invariants 8/9);
181 |     * `--no-subagents` / `--disable-web-search` – side channels that NARROW authority, which is
182 |     why the guard has never refused them. No `--allow` rule: MCP attachment comes from the
183 |     declared server, never from a pre-approval this build emits (U340);
184 |     * `-m <slug>` only when a slug was selected. `None` the CLI default, RECORDED as a fallback
185 |     by the caller (directive §11 15B, never silent).
186 |
187 |     Pure and deterministic: it builds argv. The ConPTY spawn, the I-X3 lease and the host-native
188 |     OAuth credential all stay outside this function (the credential is never read/stored/sent)."""

1  """Shared trust/emission policy for the two OP-12 frontier provider CLIs. Phase 18B `.adapter`.
2
3  Register **OP-12** (directive §17) authorized `grok_build` (CLI `grok`) and `google_antigravity`
4  (CLI `agy`). Phase 18A built the operator-facing reconnaissance tool around them; 18B `.adapter`
5  builds the headless worker adapters. Both need the SAME answers to the same four questions:
6
7      1. which environment variables must never reach a provider child (credential isolation, §13);
8      2. which arguments this build refuses to emit (tool/permission policy, §11);
9      3. what a provider's own `models` listing may be read to mean (inventory honesty, §8);
10     4. how a CLI invocation's outcome is classified (exit-code-first, §6 – the Codex-period lesson).
11
12  Those four answers live here, once. The 18A tool `tools/providers/frontier_provider_recon.py`
13  imports and re-exports them rather than keeping its own copies: a policy stated in two places is
14  how `ollama_local`-class drift starts, and the 18A gate was reopened twice over findings of exactly
15  that shape. The dependency direction is product-layer-down – the tool imports the adapter layer,
16  never the reverse.
17
18  What is NOT shared, stated so the claim is not read wider than it is: `probe_provider_cli` below
19  and the tool's own `probe_status` both sequence the same metadata calls, and they are separate on
20  purpose – the tool's answer carries diagnostics, registration state and lease state for an operator
21  reading a status report, while this one carries only what a picker may act on. They share the
22  parsers, the classifier and the auth vocabulary, which is where a divergence would actually hurt.
23  Consolidating the sequencing is the `picker` sub-step's call, once it has a real consumer (U269).
24
25  **Command-surface authority (operator directive §2).** Every flag this build EMITS, and every
26  provider-specific flag it refuses, was read off THIS host's captured `grok --help` /
27  `grok agent --help` / `agy --help` (2026-07-31, `docs/evidence/live/phase18a_host_recon.json`) –
28  never from memory. Where the operator directive quoted a flag the installed CLI does not have, the
29  installed CLI wins and the delta is recorded.
30
31  One honest exception, called out rather than folded into the claim: four entries in
32  `FORBIDDEN_PROVIDER_ARGS` (`--yolo`, `--dangerously-bypass-approvals-and-sandbox`, `--api-key`,
33  `--with-api-key`) are on NEITHER captured surface. They are Claude-Code/Codex-shaped flags carried
34  over from 18A and kept as harmless supersets, marked as such below. The first draft of this
35  paragraph said "every flag named below", which the capture falsifies – the exact direction §2
36  exists to prevent (U263).
37
38  **What this module does NOT do.** It grants no authority. Pinning a permission mode on an argv is
39  not containment in the invariant-29 sense – it is an argument the harness itself honours, and I-29
40  says never trust the harness. What IS enforced: no credential-, endpoint-, identity-, or
41  approval-widening argument can be emitted; no credential-bearing variable is passed to a provider
42  child; and the live spawn runs inside the repository's existing Windows job-object boundary
43  (`process_tree.run_managed_process`), so descendants are reaped rather than left behind. That
44  boundary is process-lifetime containment, not a filesystem/network sandbox – the latter is still
45  unbuilt for provider children (U25, owed).

160
161 # -----
162 # Argv emission policy (operator directive §11) – permission widening
163 # -----
164 # Arguments this build refuses to emit for either provider: auto-approval, permission bypass,
165 # trust widening, credential passing, endpoint redirection, agent-identity substitution, and
166 # anything that creates git/project state behind the supervisor's back.
167 #
168 # The list is ENUMERATED, not exhaustive-by-construction – it is an emission guard over argv this
169 # build itself constructs, and it claims nothing about what a provider CLI would accept from
170 # elsewhere. Each group's warrant:
171 #
172 # * approval/permission – '--always-approve' (grok) and '--dangerously-skip-permissions' (agy)
173 # are on the captured surfaces; auto-approval is exactly what §11 forbids. '--yolo' and
174 # '--dangerously-bypass-approvals-and-sandbox' are NOT on either – they are Claude-Code/Codex
175 # spellings carried over from 18A and kept as harmless supersets (U263). Refusing a flag a CLI
176 # does not have costs nothing; CLAIMING it came from the capture would have been the lie.
177 # * tool/trust widening – '--allow'/'--allowedtools'/'--tools' (permission rules),
178 # '--no-plan' (undoes the pinned plan mode), '--plugin-dir' (its own help: "always trusted –
179 # hooks and MCP servers activate without a prompt"), '--agents' (inline subagent definitions).
180 # * credential passing – '--api-key', '--with-api-key': never, on any surface (§13). Also not on
181 # either captured surface – same superset status as the two above (U263).
182 # * **endpoint redirection (U250)** – '--xai-api-base-url', '--cli-chat-proxy-base-url',
183 # '--grok-ws-url', '--grok-ws-origin', '--leader-socket'. These are the argv twins of
184 # 'XAI_API_BASE_URL', which the env scrub removes. Until now the build claimed "no endpoint
185 # override can redirect a call" on the strength of the environment half alone; the two
186 # policies agree now. '--leader-socket' belongs here for the same reason: it points the agent
187 # at an arbitrary leader process instead of the child this build supervises.
188 # * **agent identity (U250)** – '--agent', '--agent-profile'. These widen *who acts*, which is
189 # the module's own stated rationale for guarding '--agents'.
190 # * **authentication initiation** – '--reauth' starts an auth flow inside a headless child.
191 # Authentication is an explicit operator action through the runner (§5), never an adapter's.
192 # * **state creation** – '--worktree', '--worktree-ref', '--new-project'. A node's worktree is
193 # created by the Sovereign worktree-isolation path (Phase 10); a provider CLI making git or
194 # project state of its own reaches around the supervisor that is supposed to own it.
195 #
196 # Deliberately NOT here, decided rather than left ambiguous (U250 left the call to 18B):
197 # * '--cwd' (grok) and '--add-dir' (agy) BIND a workspace, which is what the isolation path
198 # needs – banning them would ban the adapter's own containment, and this build emits them
199 # itself. '--project' is NOT one of them: the capture describes it as "Project ID for the
200 # current CLI session", a session selector rather than a directory bind, and this build never
201 # emits it. It stays unbanned because U250 left the call to 18B and banning a selector nothing
202 # emits is noise – but the workspace-binding warrant does not apply to it, and grouping it with
203 # the other two by adjacency was wrong (U266).
204

```

```

205 # * `--deny` / `--disallowed-tools` / `--no-subagents` / `--disable-web-search` / `--max-turns`
206 # NARROW authority. A guard that refused them would be refusing safety.
207 # * `--leader` / `--no-leader` select a leader-process mode without naming a socket, so they are
208 # not endpoint redirection and are not banned. But they are NOT inert either, and the honest
209 # statement is that this build cannot pin them: `--leader` "Defaults to [cli] use_leader in
210 # config.toml" per the capture, and `--no-leader` exists only on the `grok agent` surface, not
211 # on the top-level `grok -p` surface this adapter uses. A node- or host-controlled config can
212 # therefore route the work into a shared leader process that is not the child this build
213 # spawns. Recorded as T2 residue (U267), not pinned, and not claimed away.
214 # * the instruction-injection flags – see `UNTRUSTED_INSTRUCTION_ARGS` (U235).

644     """Describe a provider's structured output STRUCTURALLY – key names, value types, dotted paths,
645     where `token` sits, and whether `extract_provider_response_field` can see it.
646
647     **It never reports a string or numeric LEAF VALUE.** Not as a convenience: a shape record is
648     published as evidence, so a describer that copied string values would publish whatever the CLI
649     wrote into them (§2.2/§13). String leaves are reported as paths and as `<str:LEN>` placeholders;
650     numbers are flattened to 0; booleans survive because they classify and cannot carry a secret.
651
652     **KEY NAMES ARE REPORTED, and they are provider-controlled data, not schema.** This is stated
653     rather than glossed because the first version of this docstring said "it never reports a value"
654     flatly, and the published evidence falsifies the wide reading: `modelUsage.grok-4.5.costUSD`
655     puts a MODEL IDENTIFIER from the response payload in a key position, and a CLI is equally free
656     to key a map by account or session. Key names therefore go through `redact_diagnostics` (the
657     same `SECRET_PATTERNS` every other evidence surface in this module uses) and are length-bounded;
658     what remains is a provider-controlled string in a published artifact, and a reader should treat
659     it as one. Found by the round-1 gate-validator (MEDIUM-5) and spec-auditor (MEDIUM-1).
660
661     The one deliberate exception on the value side is `token`: a string leaf CONTAINING it becomes
662     the token itself in the skeleton. That is what makes the skeleton a replayable fixture of a real
663     document – the strict reader run against `json.dumps(shape.skeleton)` answers the same question
664     it answered against the original – while the model's prose around it does not survive.
665
666     **The replay property is exactly that narrow, and both edges are load-bearing:**
667
668     * It holds for `extract_provider_response_field` ONLY. It does NOT hold for `accept_probe`,
669     because replacing a token-BEARING string with the bare token deletes the prose that echo
670     subtraction exists to remove: `{"result": "Reply with exactly: TOKEN"}` is a pure echo and
671     is REFUSED, while its skeleton `{"result": "TOKEN"}` is ACCEPTED. A skeleton is never a
672     fixture for an echo or acceptance test – that is U238/U304 territory and this would walk
673     straight back into it.
674     * Under truncation it does not hold at all, and it fails CLOSED. Past `max_nodes`/`max_depth`
675     a value becomes `null`, which no reader matches, so a truncated skeleton can lose a response
676     the original had – never invent one it did not. `null` rather than a `<truncated>` marker
677     precisely because that marker is a NON-EMPTY STRING: under a recognised key it would read as
678     a response, which is the blankness inversion below by another route (validator MEDIUM-3).
679
680     Bounded by construction (`max_nodes`, `max_depth`) – a CLI's document is untrusted input (T2) –

```

```

681 | and `truncated` says so rather than a partial description pretending to be a whole one. The
682 | bound covers the key inventory too: `top_level_keys`/`key_types` were built outside the walk and

996
997     **Raises nothing of its own.** Every provider outcome – absent binary, nonzero exit, timeout,
998     spawn error, garbage version, empty model list – becomes a `ProviderCliProbe` field, so no
999     caller has to wrap this in a `try` to stay fail-closed. What it does NOT do is swallow a
1000     RUNNER that raises: the runner's contract is to return the five-tuple (the production
1001     `subprocess_runner` catches `TimeoutExpired`/`OSError` itself and does), and a runner that
1002     raises anyway is a fault in the `harness`, not a provider outcome. The live-call tripwire
1003     `tests/live_call_guard` is exactly such a runner – it raises `SpawnRefused` to stop a
1004     deterministic test reaching a real CLI – and catching it here would silently disarm the
1005     guard. It propagates, deliberately. The docstring said the flat "Never raises" until the 18B
1006     close, which was wider than the code held (validator MEDIUM-2).
1007
1008     `reports_auth` says whether this CLI has an offline auth-reporting surface at all. Grok's
1009     `models` prints its own login line; `agy` prints nothing of the kind, and silence there is
1010     UNVERIFIED – never AUTHENTICATED (that would assume a session) and never AUTH_REQUIRED (that
1011     would be a verdict about the operator's login that nothing here observed)."""

1069 |
1070 |
1071 | class FrontierProviderCliBackend:
1072 |     """Base for the two live OP-12 backends: invokes the host's already-authenticated provider CLI
1073 |     as a one-shot headless subprocess.
1074 |
1075 |     NEVER used by the deterministic suite – every test constructs a mock or calls the pure
1076 |     `build_command`/`build_env`, which is what makes the credential (§13) and emission (§11)
1077 |     invariants verifiable without spawning anything.
1078 |
1079 |     **`generate` REFUSES, and that is a fence rather than a sentence.** An earlier draft said it
1080 |     was "reachable only from a governed live path" because no node could be registered for either
1081 |     provider while U227 was unruled. True at the time (and no longer true at all – OP-12.1 admitted
1082 |     both ids into `node@1.1`, which is precisely why leaning on it was the wrong move: the argument
1083 |     expired and the fence did not). But even then, `NodeRegistry.register` gates node
1084 |     RECORDS – it does not gate backend construction, and `build_adapter` needs only an
1085 |     `AdapterContext` whose `spawned_by_supervisor` is a caller-set bool. So the protection was the
1086 |     absence of a caller, which is not a mechanism. `_LIVE_SPAWN_PATH_WIRED` is now the mechanism:
1087 |     `generate` raises until the supervised launch path for these providers exists, exactly as
1088 |     `frontier_provider_recon.SUPERVISED_PROBE_PATH` does for the 18A probe. The flag flips in the

```

```

1089 | same commit that wires the path IT guards – the HEADLESS one this backend's `generate` runs on.
1090 | 18B `.picker` wired a different path (the supervised INTERACTIVE pane, which never calls
1091 | `generate`), so the flag correctly did not move; saying "the path" while two exist is how a flag
1092 | gets flipped for the wrong reason (spec-audit N-3). Never by config (U268).
1093 |
1094 | **Roles.** Reasoning only, and that is a decision rather than an omission. A coding role would
1095 | need either an auto-approving permission mode (`acceptEdits`/`auto`/`dontAsk` – exactly what
1096 | operator directive §11 forbids) or a sandbox profile value neither CLI documents (`grok
1097 | --sandbox <PROFILE>` enumerates none; `agy --sandbox` says only "terminal restrictions"), and
1098 | inventing one is the fabrication this build refuses. Directive **§11**'s own description of
1099 | initial provider behaviour – read assigned context, reason, respond, publish CANDIDATE output,
1100 | request protected actions through existing mechanisms – IS the reasoning role. Recorded as
1101 | U260; revisited on live evidence, never on a guess.
1102 |
1103 | **T2 – node-controlled config is untrusted.** Both CLIs read config the operator's tree or
1104 | home directory may contain (`~/grok/config.toml`, agy's project config, rules files). What a
1105 | flag ON THE SURFACE THIS BUILD USES can pin, it pins explicitly – the permission mode, the
1106 | model, the workspace, and cross-session memory (`--no-memory`) – so a config default cannot
1107 | supply something more permissive. That qualifier is load-bearing and was missing from the first
1108 | draft: `--no-leader` exists only on the `grok agent` surface, so leader mode genuinely cannot
1109 | be pinned from `grok -p`.
1110 |
1111 | Residue, recorded rather than claimed away (U259, the same class as the Codex adapter's U32):
1112 | MCP servers and hooks declared in host config; plugin scopes already installed; and leader mode
1113 | (U267), which a config can enable to route work into a process this build did not spawn and
1114 | does not reap.

2 |
3 | `adapters/local/worker.py` is the headless local worker (a `LocalWorkerAdapter` driving the Ollama
4 | HTTP API through the governed adapter contract). This module builds the OTHER shape 17B needs: the
5 | argv for an interactive `ollama run <tag>` session the operator can watch and type into in a pane –
6 | the local half of the operator's definition-of-done (c) ("selecting a model on a pane, incl. local
7 | `qwen3:8b`, launches that live worker, governed").
8 |
9 | Deliberately tiny and deterministic. Two rules it enforces, both fail-closed:
10 |
11 | * a model TAG is required and must be a tag, not a flag – an argument beginning with `-'` would be
12 |   read by the CLI as an option, so a caller cannot smuggle one through the model field;
13 | * no prompt argument is ever appended – `ollama run <tag>` with a trailing prompt is the one-shot
14 |   mode, and an interactive pane session is the point here.
15 |
16 | Locality (invariant 19/20): a local model involves NO subscription and NO credential, so nothing in
17 | this path reads or transmits one – the governance that applies is VRAM residency (invariant 22),
18 | enforced by the caller through the ResidencyPlanner before this argv is ever launched.

35    (and its limits) are honest.
36
37    Phase 16E `.real` fix (OP-10 host-fact defect): NeMo is probed *inside WSL2* (a timeout-bounded
38    `wsl.exe` import check), NOT via a HOST `import nemo` – the latter is structurally always false here
39    because NeMo lives in the WSL env and Windows has no MSVC to build its stack, so real Parakeet was
40    never selected even when installed. The WSL probe is fail-closed: no WSL, no venv, a non-zero exit,
41    or a timeout each read as `nemo:false`.
42
43    Phase 17C `.probe` (U74) adds the THIRD answer the pre-U74 shape could not express. `nemo` is a
44    boolean, so "we have not asked yet" had to be reported as False – which the chrome drew as "mock
45    engine" on a host with Parakeet installed (finding F1). So detection now also carries
46    **`nemo_state`**: `available` / `unavailable` / `unprobed`, and callers that must not block
47    (the always-visible indicator poll) pass `blocking=False` to get the cached answer or `unprobed`
48    WITHOUT spawning WSL. `nemo` stays fail-closed – True only for a real, positive probe.
49
50    `force=True` re-probes now, ignoring the cache (the "re-probe on demand / after failure" path).

1 | """Real NVIDIA Parakeet STT adapter over WSL2 – Phase 16E `real` (directive $15 track 16E; OP-10;
2 | OP-9/$10.3 authorizes the NeMo stack). Closes the operator's host-fact defect: the mock-vs-real
3 | detection probed `import nemo` in the HOST Windows interpreter (structurally always false – NeMo lives
4 | in the WSL2 env, and Windows has no MSVC to build its numpy stack), so real Parakeet was NEVER
5 | selected even on a host where it is installed. This module probes NeMo *inside* WSL (timeout-bounded)
6 | and routes transcription through the WSL env interpreter, behind the same `STTEngine` contract the mock
7 | implements (agnosticism lives in the interface – I-A1).
8 |
9 | Honesty / fail-closed (invariant 3 / invariant 20 spirit; directive $15 track 16E – *"never silently
10 | pretend to hear"*): a missing WSL, a missing env/NeMo, a non-zero exit, a timeout, or malformed output
11 | each read as "real Parakeet not available" (→ the visible mock, at the selection layer) or, for a
12 | transcription fault, a raised `VoiceEngineError` the caller folds into the fail-closed feed – never a
13 | fabricated transcript. STT-only (I-V2/D-VOICE-02): there is no synthesis method here by construction.
14 | Audio is transcribe-then-discard (invariant 26): the adapter neither copies nor retains the WAV.
15 |
16 | MOCK-FIRST still governs the headless read-source (`.engine`): the real engine is selected ONLY for a
17 | real capture (`.for_capture=True`) with a real WAV – the stand-in `audio:` refs the shell's indicator
18 | poll uses carry no PCM and stay on the mock. No credentials, no network from this module (the WSL env
19 | was operator-installed per docs/OPERATOR_NEMO_INSTALL.md); `wsl.exe` is a local process (directive
20 | $2.2/$2.4 – no `claude`/`codex`, no secret).
21 | """

35 | from adapters.frontier.process_tree import run_managed_process
36 | from adapters.voice_parakeet.engine import Transcript
37 |
38 | #: The engine name the shell surfaces as the VISIBLE real-STT badge (never "mock-stt").
39 | PARAKEET_WSL_NAME = "parakeet-wsl"
40 |
41 | #: Default model ref (CC-BY-4.0; U4 attribution). The operator install caches it in WSL.
42 | DEFAULT_MODEL_ID = "nvidia/parakeet-tdt-0.6b-v3"
43 |
44 | #: How long a WSL probe/transcription may run before it fails closed. Both are hard bounds – a hung WSL
45 | #: can never wedge the shell or the loop (D-P16-0 / D-LOOP-1 spirit).
46 | #:
47 | #: U74 / OP-11 finding F1 (2026-07-25): the operator's shell badged "mock engine" on a host where WSL
48 | #: Parakeet is INSTALLED AND VERIFIED, because this budget was 8.0 s. Two facts, both MEASURED on this
49 | #: host on 2026-07-26 (recorded in docs/evidence/PHASE17C_PROBE_EVIDENCE_REPORT.md):
50 | #: * the old probe body (`.import nemo`) is a ~0.04 s namespace-package import that says NOTHING about
51 | #: whether ASR can run – so it was both slow-to-fail and weak-when-it-passed;
52 | #: * the import transcription ACTUALLY performs (`.from nemo.collections.asr.models import ASRModel`)
53 | #: costs **17.91 s** on a cold page cache and **7.02 s** warm – already past 8.0 s by itself,
54 | #: before `wsl.exe` VM start (measured separately at 4.46 s cold on this host).
55 | #: So the probe now runs the import that matters, under a budget set from that measurement with room for
56 | #: a cold VM: 90 s (directive $16 track 17C requires ≥60 s). Env-overridable – never a wired-in guess.
57 | PROBE_TIMEOUT_S = 90.0
58 | TRANSCRIBE_TIMEOUT_S = 180.0
59 |
60 | #: How long a probe RESULT may be reused before it is re-taken. The old code cached the first answer for
61 | #: the life of the process (`.functools.lru_cache(maxsize=1)`), which pinned ONE cold miss for the app's
62 | #: whole run – the second half of U74. A positive answer is stable (the env does not uninstall itself
63 | #: mid-session) so it is held for 15 min; a NEGATIVE answer is held only long enough to stop a poll storm
64 | #: (30 s) and is then re-taken, because "not available" is exactly the state that changes when WSL warms
65 | #: up, the operator finishes an install, or a transient VM start fails.

279     That is U74's failure re-staged at the process boundary: the shell KNOWS the engine is reachable
280     (`VoiceProbe` maintains that fact and paid 7-22 s for it), it just could not say so across the seam.
281
282     This is the seam. The shell passes the answer it holds; nothing is fabricated, because a seeded
283     POSITIVE cannot manufacture a transcript – `WslParakeetSTT.transcribe` still runs the real WSL
284     round trip and still fails closed (`VoiceEngineError` → the unavailable feed) if NeMo is not
285     actually there. The only thing a seed can do is skip a redundant 20 s import; the honest direction
286     is preserved in both directions, and the provenance rides in the reason (`SEDED_REASON_PREFIX`).

1  """Conductor SELECTION state – Phase 15D `.selection` (directive §11 track 15D).
2
3  The conductor is an INTERFACE plus a runtime selection (invariant 3 / I-CN1): "conductor" is never a
4  vendor default and never the name of a model. The operator's current selection is **fable-5**
5  (`reason: operator_selected`, OP-6). This module is the single deterministic source of that record
6  and of the one distinction 15D turns on:
7
8      SELECTION = what the operator chose      (fable-5 – an interface label, stable)
9      REQUESTED = what was asked of the CLI    (the `--model` slug, or none CLI default)
10     EXECUTING  = what actually ran            (the checkpoint id a LIVE reply reported)
11
12  All three are recorded SEPARATELY and none is inferred from the others. `executing.model` is
13  **None until a live reply reports a checkpoint id** – a conductor that was refused at a gate, or a
14  mock run, executed nothing, and this record says so rather than echoing the requested slug back as
15  though it had run.
16
17  Vendor neutrality (invariants 3, 4, 20): this module imports NO adapter. Slug resolution is a
18  provider-neutral default that any adapter-specific resolver may replace via `resolver=`, so a
19  successor conductor on a different backend (codex, a local Ollama model) binds through the same
20  path. The pinned selection's `adapter` field is a plain recorded string; a test pins it structurally
21  to the adapter constant so the two cannot drift without a failing test.
22
23  Fail-closed rules (Buildout §4): the reason enum and the record's key set are read from the FROZEN
24  `checkpoint@1.0` `current_conductor` definition (never a local copy that could disagree); a blank
25  model, an unknown reason, a non-date-time timestamp, a non-mapping record, or a smuggled extra key
26  all RAISE; `executing_verified` is True only when a live reply actually reported a checkpoint id; an
27  unavailable model resolves to the CLI-default **recorded** fallback (directive §11 15B – never
28  silent). No clock is read here – every timestamp is injected, so records are deterministic.
29
30  `executing_verified` is True ONLY when the caller supplies an `ExecutingEvidence` (U45, discharged
31  at `phase-15d.gate`). A bare `reported_model` string – which any caller could produce, with no type
32  and no freshness scoping – is recorded as an UNVERIFIED claim and never becomes a checkpoint.
33
34  This module holds NO authority: it labels and records; it does not spawn, authorize, or select on
35  the operator's behalf (invariant 1).

260 |     """Bind the conductor selection to a backend, honestly.
261 |
262 |     `requested_model` defaults to the selection's own model, so the conductor asks for **fable-5**
263 |     rather than silently accepting whatever the CLI defaults to (directive $11 15D: "model_ref =
264 |     fable-5 if available else recorded fallback").
265 |
266 |     `model_available=False` records the fallback branch of that requirement (backend default +
267 |     RECORDED note). `None` means "not probed", and is still the honest state for any backend with no
268 |     probe behind it. For `claude_code` that probe now EXISTS and is in the production path
269 |     (`adapters.frontier.claude_model_probe` + `tools/live/probe_conductor_model.py`, Phase 17A
270 |     `roundtrip`): the launch ticket and the badge feed pass True/False through this parameter from a
271 |     recorded live observation, and an undecidable probe deliberately passes None so the operator's
272 |     selection is carried verbatim rather than demoted.

```

```

273 |
274 |     `executing_evidence` is the ONLY route to a verified executing checkpoint (U45, discharged at
275 |     `phase-15d.gate`). It carries a checkpoint whose caller applied the vendor-side rule – exact CLI
276 |     class, a call spent, a checkpoint the CLI itself reported, stamped by a call made after the
277 |     caller's bind-time snapshot.
278 |
279 |     `reported_model` is a RAW, UNBACKED claim and can no longer verify anything. It is retained
280 |     because dropping it would hide that a claim was made: it is recorded verbatim under
281 |     `reported_unverified` and named in the note, while `executing.model` stays None. Passing BOTH a
282 |     bare claim and evidence that disagree RAISES – a record must not present one as the other.

1 | """Shell <-> control-plane IPC (Plan section 5, row "Shell <-> control plane IPC";
2 | decision D-IPC-01).
3 |
4 | D-IPC-01 verdict (operator-delegation, ruling 2026-07-16): the shell <-> control-plane
5 | transport is a **loopback WebSocket carrying schema-validated envelopes** – the canonical
6 | plan's recommendation, adopted as the default. WebSocket (not raw NDJSON like the MCP
7 | transport, U6) is chosen because the desktop shell's connecting side is a Chromium/Node
8 | process for which WebSocket is the native client; a hand-rolled RFC 6455 server on the
9 | Python stdlib keeps us inside the build's no-pip constraint (prohibition 2.7) exactly as the
10 | MCP transport did.
11 |
12 | Governance path proven here (this is the system under test, not the byte framing):
13 | - per-node AUTHENTICATION at the transport (bearer credential, fail-closed) – reused from
14 |   the MCP credential pattern (mcp_server/auth.py); MCP holds no authority (I-M2) and
15 |   neither does this gateway beyond authenticate-then-forward;
16 | - every message is an ``envelope@1.0`` (schemas/message.schema.json, Plan 9.2) – the ONLY
17 |   control channel (TB-2); terminal text is never parsed as a command;
18 | - INTEGRITY: hmac-sha256(payload) verified against the per-connection shared key
19 |   (fail-closed on mismatch); responses are signed the same way so the shell can verify
20 |   the control plane;
21 | - fail-closed on bad auth, bad schema, bad integrity, oversized frame, or disconnect.
22 | """
```

```

1  """Reference IPC client (Python, stdlib) for the loopback-WebSocket control channel.
2
3  Two roles:
4  - it is the client used by the IPC test suite;
5  - it is the reference the desktop shell's Node/Chromium client mirrors (same handshake,
6    same signed-envelope contract) – the shell uses a native WebSocket, but the message
7    framing and the compute/verify of integrity are identical.
8
9  Fail-closed: any transport fault raises IpcDisconnected; a response whose integrity does not
10 verify raises IpcIntegrityError. Callers must not proceed on unverified control-plane state.

1  """Minimal RFC 6455 WebSocket framing on the Python stdlib (no pip, prohibition 2.7).
2
3  Scope is deliberately the subset the shell <-> control-plane channel needs: a single
4  loopback connection, text messages carrying one JSON envelope each, plus the mandatory
5  control frames (close/ping/pong). It is NOT a general-purpose WebSocket stack – no
6  extensions, no permessage-deflate, no streaming fragment API beyond reassembly.
7
8  Correctness points that matter for the trust boundary:
9  - a server MUST reject an unmasked client frame and a client MUST reject a masked server
10     frame (RFC 6455 section 5.1); we fail closed on both;
11  - payload length is bounded (MAX_MESSAGE) so a peer cannot force unbounded buffering
12     before the envelope is even parsed (mirrors the MCP pre-auth bound, spec-audit F6);
13  - reads that hit EOF raise WsClosed so callers fail closed rather than spin.

1 | """Per-pane model picker data model (OP-7 §12.2 – Phase 15E `picker` ).
2 |
3 | OP-7 §12.2: *every pane gets a model selector offering both live provider adapters with their
4 | probed model IDs (Anthropic: Opus 4.8 / Fable 5 / CLI default; OpenAI: the GPT-5.5 line incl.
5 | Sol as probed), **and** the operator's entire local model list enumerated live from
6 | `ollama list`. Selecting spawns a governed node through supervisor + governor (naked sessions
7 | still refused). Local models route through the VRAM residency planner; the picker shows
8 | residency state (resident / loading / awaiting-eviction).*
9 |
10 | This module is the **pure, deterministic, fail-closed** data layer that produces that option
11 | list. The rendered selector is an operator-run surface (Phase-1 substitution pattern); this is
12 | the JSON it consumes, built here so the picker can never fabricate an option or hide an
13 | unavailable one. Spawning is a LATER sub-step (`.spawn`); this only *offers* – every option
14 | carries an `available` flag with a recorded reason so the picker greys-out (never hides) a
15 | provider that live authorization does not cover.
16 |
17 | Honesty rules enforced here:
18 | * a frontier provider is `available` ONLY if `LiveAuthorization` covers it (fail-closed to
19 | unavailable-with-reason otherwise – never hidden, per invariant 20 air-gap honesty spirit);
20 | * the Codex option also requires the CLI to be present AND authenticated on the host (the
21 | caller passes those facts from a real `probe_codex`) – each missing condition is named;
22 | * frontier model slugs are never fabricated. For the OP-6 pair they are UNVERIFIED operator
23 | labels until a live smoke (`.verified` carried straight from the roster descriptor). For the
24 | OP-12 pair the slug IS the CLI's own `models` listing, so it ships `verified=True` on a
25 | stronger basis than an operator label – the CLI said it (see `_op12_options` and U272). Two
26 | different bases, one rule: the flag reports where the slug came from and is never upgraded
27 | downstream (`.worker_pane_spawn` carries it verbatim);
28 | * local Ollama models need no credential (§2.4) so they are always offered when enumerated,
29 | each annotated with its live residency state from the ResidencyPlanner; an empty
30 | enumeration yields zero local options RECORDED (never a fabricated model).

303 |     """Options for one OP-12 provider - one per model the CLI ITSELF enumerated, never more -
304 |     together with the group-level reason (None when the provider is fully available).
305 |
306 |     Three differences from the claude/codex builders above, each forced by what these CLIs are:
307 |
308 |     1. **There is no candidate-label list and no "CLI default" option.** `claude`/`codex` publish no
309 |     offline model list, so the picker offers operator LABELS resolved at launch. These two DO
310 |     publish one (`grok models`, `agy models`), so the option set IS that listing - an id this
311 |     build never composed. A provider with an empty listing therefore yields ZERO options: the
312 |     directive says model identifiers are never invented, and "CLI default" for a provider whose
313 |     real default we could not read would be exactly that invention.
314 |     2. **`verified=True`.** In this codebase the flag means "the CLI confirmed it accepts this id",
315 |     which is precisely what an entry in the CLI's own listing is (the same basis on which
316 |     `roster_descriptor` sets it, and on which a local Ollama tag is verified). It does NOT mean a
317 |     live session has answered - nothing offline can establish that, and the note says so.
318 |     3. **Authentication is per-provider and asymmetric**, because the hosts' surfaces are: `grok
319 |     models` prints its own login line, so `authenticated=False` is a real refusal condition;
320 |     `agy` prints nothing about auth ever, so `None` blocks nothing and is disclosed in the note
321 |     instead. Blocking on it would make the provider permanently unselectable on a signed-in host;
322 |     claiming it is fine would be an auth claim nothing observed ($6).
323 |     """

462 |     fail-closed.
463 |
464 |     `live`           – resolved LiveAuthorization (frontier availability gate).
465 |     `ollama_models` – the operator's live `ollama list` result (host-enumerated by the
466 |                       driver; None/[] no local options, recorded honestly).
467 |     `residency`     – ResidencyPlanner.residency_map(): local model → residency state.
468 |                       `None` means there is NO residency view (the daemon is unreachable, or
469 |                       the VRAM budget could not be established so no planner exists) and every
470 |                       local model renders UNKNOWN – never NOT_LOADED, which would assert a
471 |                       fact about a model the daemon may be serving right now.
472 |     `claude_available` – real `detect.claude_code_available()`: is the `claude` CLI on PATH?
473 |     `codex_available` – real `probe_codex` result: is the `codex` CLI on PATH?
474 |     `codex_authenticated` – real `probe_codex` result: is it logged in?
475 |     `local_unavailable_reason` – when the VRAM budget this host's local admission gate needs could
476 |                               not be established, every local option is greyed with THIS reason (the

```

```

477 |         authorization would refuse it – spec-audit MAJOR-2). None    offered.
478 |         `grok` / `antigravity` – the OP-12 provider inventories from a real host probe
479 |         (`ProviderCliInventory`). None    that provider is offered with ZERO
480 |         options and the reason says the CLI was not detected – never a
481 |         fabricated model, and never a silently absent provider.
482 |
483 | Returns a dict with `providers` (grouped) and a flat `options` list (the UI can render
484 | either), plus `authorization` provenance and honest counts. Nothing is hidden: an
485 | unavailable provider's options appear with `available=False` and a specific reason – and a
486 | provider with NO options at all carries that reason on its GROUP (`status`), which is the only
487 | place it can live for the OP-12 pair: their option sets come from a live enumeration, so an
488 | absent or signed-out CLI legitimately produces an empty list, and an empty list with no reason
489 | would render as a silent gap exactly where the honesty matters most.

1  """Node registry: single state authority for node incarnations (Plan sections 7-P2, 9.1).
2
3  Every mutation validates the state machine and lands in the append-only event log before
4  the in-memory view changes – the log is the record, the dict is a cache of it. I-C1 is
5  enforced at registration: a process not spawned by the supervisor is refused. PAUSED
6  resumes only to the state it interrupted. TERMINATED is absorbing; a restart registers
7  the next incarnation under the same node_id.
8
9  **Adapter vocabulary (18B `scope` → 18D, U227).** `adapter` is a node schema field with a frozen
10 enum, and until 18B nothing checked it: `register()` took any string. That was tolerable while the
11 only out-of-enum id was `ollama_local` (a local, un-counted node), and it stopped being
12 tolerable the moment Phase 18 asked to register subscription-backed frontier providers whose
13 ids the canonical vocabulary does not contain. The claim "no schema-valid node record can name
14 these providers" needs to be a property of the code, not a sentence in a docstring – because the
15 event log is APPEND-ONLY (invariant 12), so a node record written under an unrecognised adapter
16 cannot be un-written later.
17
18 So registration refuses an `adapter` that no version of the node schema admits. **The operator
19 ruled U227 on 2026-08-01 (OP-12.1, directive §17.1): by SUCCESSOR SCHEMA, not by editing the
20 freeze.** `schemas/node.schema@1.1.json` exists beside the untouched `@1.0` and adds exactly three
21 members – `grok_build`, `google_antigravity`, and `ollama_local` (the U254 drift, admitted by the
22 same ruling). This module's vocabulary is therefore the UNION over every node schema version
23 present, read from the files; `grok_build` and `google_antigravity` now register, and an id in
24 NEITHER version is still refused with an auditable `registration_refused` event naming the versions
25 that were consulted.
26
27 Two properties of that union are deliberate. It is derived, never re-declared – a hand-written copy
28 of an enum is the drift this guard exists to catch. And it is fail-closed in both directions: an
29 unreadable or malformed schema file contributes NOTHING (so a corrupted `@1.1` refuses the new
30 providers rather than defaulting them open), and a version whose enum is unreadable cannot widen
31 anything. `register()` records WHICH version admitted the adapter on the append-only spawn event,
32 so an auditor reading the log can tell a `@1.0` node from one admitted by the amendment.

45
46 #: The schema directory, monkeypatchable in tests so the fail-closed branches can be MEASURED
47 #: against a corrupt/missing file rather than argued for. `_SCHEMA_PATH` (the single-file constant
48 #: this replaced) is gone rather than kept "for compatibility": it had no reader left, and a stale
49 #: pointer at the frozen file is precisely how a second, narrower vocabulary source comes back.
50 _SCHEMA_DIR = Path(__file__).resolve().parents[2] / "schemas"
51
52 #: The node schema versions this registry consults, in precedence order: the frozen Phase-0 file
53 #: first, then every recorded successor. A successor is a FILE, not a literal – adding a version
54 #: means writing the schema, extending the freeze manifest's amendment block with its authorizing
55 #: operator ruling (OP-12.1 / U222), AND adding a row to this tuple. The third act is the one that
56 #: actually changes runtime behaviour, and it is named last here on purpose: the first two are the
57 #: reviewable record, this is the switch. A named file that is absent is skipped, not fatal: the
58 #: union simply stays narrower, which is the safe direction.
59 NODE_SCHEMA_VERSIONS: tuple[tuple[str, str], ...] = (
60     ("node@1.0", "node.schema.json"),
61     ("node@1.1", "node.schema@1.1.json"),
62 )
63
64 #: Adapter ids allowed to register while being members of NO node schema version. **Empty since
65 #: 18D, and that is the point of the amendment.** It held exactly one id – `ollama_local`, the
66 #: local Ollama adapter every product path has used since Phase 15E while the frozen enum spells
67 #: the same thing `ollama_direct` (U254) – grandfathered here rather than tolerated silently.
68 #: OP-12.1 admitted that id into `node@1.1` itself, so the grandfather clause has nothing left to

```

```

69 | #: cover and the vocabulary is now schema-derived with no exceptions at all.
70 | #:
71 | #: The mechanism is kept (not deleted) because it is the recorded, reviewable place for a future
72 | #: id that genuinely cannot wait for a schema version – but note that an EMPTY set is strictly
73 | #: stronger than a populated one, and the honest bar for adding a row is now higher, not lower:
74 | #: OP-12.1 shows the schema route is available. There is no bypass parameter; the
75 | #: `allow_unlisted_adapter=True` opt-out the guard first shipped with had no caller anywhere
76 | #: (spec-audit MINOR-5, 18B close) and is gone.

239 |     """Restore ONE record into the in-memory view **from the durable log**, writing nothing.
240 |
241 |     The module docstring says it plainly – "the log is the record, the dict is a cache of it" –
242 |     and until 18E nothing could act on that: `NodeRegistry` starts empty and never replays, so
243 |     a SECOND PROCESS reading a durable log could see every event and still not `get()` a node.
244 |     That is exactly the world the worker-pane lifecycle lives in: the ticket is one `py -3.12`
245 |     invocation, the spawn attestation another, the release a third. Without this, closing a
246 |     record written by an earlier process was impossible and the only reachable behaviour was to
247 |     register the same pane again as a fresh incarnation on every step.
248 |
249 |     It is a CACHE restore and nothing more, so it is deliberately the weakest method here:
250 |     it appends no event (there is nothing new to record – the caller is reading back what the
251 |     log already says) and it grants no authority. THREE fences, because dropping any would make
252 |     it a bypass of the ones `register()` exists to be:
253 |
254 |     * the vocabulary check – an adapter no node schema version admits is refused, since a
255 |     record that could not be WRITTEN must not become readable by another door;
256 |     * the duplicate guard – rehydrating over a live key would silently discard the in-memory
257 |     state of a running node;
258 |     * **the log must actually carry a `spawn` row for this exact `(node_id, incarnation)`.**
259 |     The first cut asserted this in prose ("the caller has to have read the record out of
260 |     the log to pass one in") and enforced nothing, so any in-process caller could hand in a
261 |     fabricated `NodeRecord` and then drive it through `transition`/`record_exit` – which DO
262 |     append – producing `transition`+`exit` rows for a node with no `spawn` row, defeating
263 |     the spawn/exit pairing `event_log` names as the compensating control for the chain's
264 |     tail-truncation blind spot (spec-audit MINOR-8). The claim is now the check.
265 |
266 |     Unlike `register()`, a refusal here appends NO `registration_refused` event: nothing was
267 |     being written, and an append-only log is not the place to record that a reader asked a bad
268 |     question.

1 | """Governed CONDUCTOR dispatch feed – Phase 16C `.dispatch` (directive §15 track 16C; OP-8 §13.4 / OP-9).
2 |
3 | The govern-born conductor pane (`.spawn`) is not just a chat surface: as it converses it DISPATCHES work
4 | to the other model nodes over the shared Sovereign MCP memory, pulls their CANDIDATE results back through
5 | the gates, and SYNTHESIZES them (OP-8 §13.4). This sub-step wires that dispatch into the shell so the
6 | operator can see, on launch, that the conductor's governed dispatch path is real – it runs the whole
7 | `control_plane.orchestration.live_flow` loop (decompose → assign BY DESCRIPTOR → CANDIDATE over MCP →
8 | real gate engine → conductor synthesis into an acceptance packet) and folds the trace into a stable
9 | `conductor_dispatch_feed@1.0` contract the renderer draws from.
10 |
11 | HONESTY – this is the load-bearing constraint (directive §6 / §10.4; closes **U58 as far as evidence
12 | allows**). U58 records that the live `.flow` proved a live CONDUCTOR but the WORKERS were still the
13 | deterministic `LocalWorkerAdapter` (`.legs.workers="mock"`). This sub-step does NOT change that: the
14 | dispatch is run MOCK-first – `legs.conductor="mock"`, `legs.workers="mock"` – so **no live model call is
15 | made here** (§2.2/§2.4), and `build_acceptance_packet`/`.assert_legs_honest` make a `live`/`.attempted`
16 | WORKER leg UNREPRESENTABLE without its own evidence record. The feed therefore carries an explicit
17 | `live_workers_owed` record: the governed dispatch MACHINERY is proven end-to-end and wired into the shell,
18 | but the actual LIVE worker CANDIDATE publication remains OWED to the operator-run assembled run (16F). We
19 | close U58 exactly as far as the non-interactive evidence allows and no further – never dressing a mock
20 | dispatch as a live-worker result.
21 |
22 | Invariants surfaced on the feed so an operator/self-check can verify them: routing is BY DESCRIPTOR
23 | (invariant 4 – `by_descriptor`), the conductor does not accept its own synthesis (invariant 18 – the
24 | `acceptance_verdict` is the GATE node's, and the packet's `operator_disposition` stays `pending` because
25 | gate promotion is NOT operator acceptance, invariant 1). Fail-closed (invariant 3 / invariant 20 spirit):
26 | any fault yields the UN-DISPATCHED feed (`.dispatched:false`, `reason`), never a fabricated dispatch.
27 | D-LOOP-1 (directive §14): the MCP server + flow are torn down within `run_governed_dispatch` before it
28 | returns (`.torn_down:true`) – nothing outlives the call.
29 | """

274 | ) -> dict[str, Any]:
275 |     """Run ONE governed dispatch over a REAL loopback MCP server and return the folded feed, tearing
276 |     the server + flow down before returning (D-LOOP-1).
277 |
278 |     DEFAULT: mock-first – no `worker_handles`, so NO live model call is made and the feed carries the
279 |     honest U58-owed record. This is what the shell invokes on launch, and it must stay that way: an
280 |     app launch may never spend the operator's subscription.
281 |
282 |     `worker_handles` (Phase 17B `.legs`) is a factory called with `(server, project_id)` AFTER the
283 |     server is up, returning already-spawned `WorkerHandle`s – a live one comes from
284 |     `live_flow.live_claude_worker_handle`, i.e. through the governed live-spawn gates. The factory is
285 |     injected rather than parameterised so this module never imports a live-spawn path (nothing here
286 |     can spawn a vendor CLI by accident), and the flow releases each handle's I-X3 terminal on close
287 |     (D-LOOP-1). A factory that raises propagates to the fail-closed wrapper – an un-dispatched feed,
288 |     never a fabricated one.
289 |
290 |     `store_root` is a caller-owned directory (a tempdir in the emitter/tests) – this function never
291 |     touches anything outside it. `clock` defaults to the fixed replayable `DISPATCH_TS`.

1  """Conductor voice-IN feed – Phase 16E `.engine` (directive $15 track 16E; OP-8 $13.5; closes the
2  READ half of U67).
3
4  OP-10 first-use finding (3): *"voice unusable"*. Phase-15E `.voice` shipped the routing AUTHORITY
5  (`voice_bridge/conductor_voice.ConductorVoiceBridge` over the real `CommandBroker`) and the pure JS
6  render model, but the shell's `voice:propose` only RECORDED a push-to-talk hold – no engine was
7  selected, no transcript produced, nothing routed (**U67**). Track 16E closes that end-to-end. This
8  `.engine` sub-step delivers the honest, engine-SELECTED read half: pick the STT engine (real Parakeet
9  only when the host stack is present AND a real adapter exists – track 14D; otherwise the mock behind
10 the same `STTEngine` contract, ALWAYS surfaced as a VISIBLE mock engine, never a silent
11 pretend-to-hear), route ONE captured utterance through the REAL bridge over a REAL broker, and fold the
12 `ConductorInputOutcome` into the stable `conductor_voice_feed@1.0` JSON the shell renders – the SAME
13 bounded `py -3.12` read-source pattern the 16B picker and the 16C/16D feeds use.
14
15 The `.wire` sub-step then connects the shell talk button to this feed and DELIVERS a CHAT outcome into
16 the conductor's ConPTY input (the operator-run write, D-P16-0 in-Electron self-check). Here the
17 `ConductorChatSink` is a recording sink – the headless stand-in for that write.
18
19 MOCK-FIRST, no live call (directive $6 / $10.4): the bridge runs the mock STT + a mock/local broker,
20 so `--emit-conductor-voice` NEVER spawns a `claude`/`codex` process ($2.2/$2.4). NO speech-OUT
21 (I-V2/D-VOICE-02): the bridge exposes no synthesis method by construction; `tts:False` is carried
22 through the feed. Audio is transcribe-then-discard (invariant 26); the `audio_ref` is a capture
23 stand-in (no real PCM), discarded by the adapter's policy.
24
25 Fail-closed (invariant 3 / invariant 20 spirit): any fault the UNAVAILABLE feed (`sourced:false`,
26 `reason`, a CLARIFY outcome, `mock` engine) – a 0-exit JSON line the shell renders as "voice
27 unavailable", never a fabricated "delivered to the conductor".

54 #: verb, so the bridge delivers it as ordinary CHAT – the delivery half of the voice-IN path.
55 DEFAULT_AUDIO_REF = "audio:show-status"
56
57 #: The honest U67/16F record carried on the STAND-IN feed: with a PCM-less `audio:` ref, real mic
58 #: capture and the interactive conductor ConPTY write are both operator-run surfaces.
59 LIVE_CAPTURE_OWED: dict[str, Any] = {
60     "owed": True,
61     "issue": "16F",
62     "note": ("the ROUTING is real (bridge + broker) and the transcript is engine-selected, but real "
63            "microphone capture and the write of a CHAT transcript into the interactive conductor "
64            "ConPTY are the operator-run surfaces (a real PCM stream, an admitted live conductor "
65            "session) – the assembled-run evidence is owed to 16F."),
66 }
67
68 #: Phase 17C `.mic`: what is ACTUALLY still owed once a real WAV has been transcribed. Repeating the

```

```

69 #: stand-in record on a feed that just ran real PCM through real WSL Parakeet would be a false OWED.
70 #:
71 #: But an OWED record that UNDERSTATES is the more dangerous error, because nobody re-checks a debt
72 #: that has been declared paid – it is how a gate gets closed over incomplete work. An earlier revision
73 #: of this constant said the microphone was the ONLY remaining debt, on the same feed whose `note`
74 #: reported the conductor ConPTY write as owed: one object asserting both. TWO things remain, and both
75 #: are named here. Directive $16 track 17C requires "*" to the LIVE 17A conductor session"*, and that leg
76 #: is not discharged by delivering into an admitted stand-in pane.
77 #:
78 #: Phase 17C `.close` discharges the SECOND of those two debts and says exactly how. What is left is the
79 #: operator's own microphone – and it stays `owed: True` for that reason, because the debt that remains
80 #: is the one no automated check can ever reach.
81 REAL_CAPTURE_OWED: dict[str, Any] = {
82     "owed": True,
83     "issue": "17C.mic",
84     "note": ("real PCM was transcribed by the selected engine and routed by the real bridge – the "
85             "capture, the engine selection and the routing WIRING are no longer owed. What remains: "
86             "(1) the operator physically speaking into a microphone, which no automated check can "
87             "reach (directive $16 track 17C – the spoken-mic half is operator first use); and (2) the "
88             "routing is WIRED, not CALIBRATED – see `routing_limits` below. Neither is discharged by "
89             "any receipt."),
90     #: Phase 17C `.close` (spec-audit MAJOR-6). Saying "the routing is no longer owed" without this
91     #: would be the understatement that matters: the two deterministic barriers in front of a LIVE
92     #: conductor that can act are (a) an STT confidence that is derived from recognition rather than
93     #: measured, so the bridge's low-confidence CLARIFY branch cannot fire on the real engine, and
94     #: (b) a deterministic full-utterance lexicon, not semantic intent classification. Both are
95     #: registered, and this record – the
96     #: one carried on every real capture feed – has to name them, because a debt that only appears in
97     #: an evidence report is a debt the running system never mentions.
98     "routing_limits": (
99         "U140: on the real engine confidence is 1.0 for any non-empty transcript (NeMo emits a "
100         "log-probability, not a 0..1 score), so the bridge's low-confidence CLARIFY branch protects "
101         "against silence, not against mishearing. U144 (NARROWED by phase-17c.close-revalidate): "
102         "protected/destructive verbs, synonyms and common inflections are scanned across the WHOLE "
103         "utterance, so polite prefixes no longer evade the broker; arbitrary semantic paraphrases "
104         "outside that deterministic lexicon are not intent-classified. Production direct CHAT is "
105         "therefore marked as a supervisor-owned non-executing voice turn: the launch-bound hook denies "
106         "every tool call and permission escalation until that turn stops. Vendor mode chrome is "
107         "interaction state only and never authority (invariants 25/29)."),
108     ),
109     #: The delivery destination is a PER-CAPTURE fact this producer cannot observe: it emits the routing
110     #: verdict, and the shell then writes (or honestly cannot write) into pane 1's ConPTY. So this field
111     #: records the CAPABILITY and its evidence, and names the field that answers for the current
112     #: utterance – never a blanket claim that this capture reached a live conductor.
113     "live_conductor_write": (
114         "the supervisor-owned non-executing voice-turn boundary is wired into the governed conductor "

1  """Phase 15D `.debate` – ONE bounded debate driven through the LIVE-capable model binding.
2
3  Directive §11 15D: "one bounded live debate (budgets enforced – real tokens now)". The Debate
4  Service itself already exists and is gated (Phase 7, `gate/phase-7`): ≤5 rounds, evidence-cited
5  assertions, dissent preserved verbatim, per-debate budget + per-caller quota + global concurrent
6  cap, clean budget-exhaustion cutoff, any authorized (non-conductor) node may call. This module
7  adds ONLY what 15D needs on top of it:
8
9  1. `BackendDebater` – a `Debater` backed by any `Backend`, so the SAME governed debate runs on
10     a mock backend or on the live `claude_code` CLI with no branch in the service.
11  2. A FAIL-CLOSED statement parse: a model reply that is not well-formed becomes a recorded
12     refusal with NO citations (hence UNSUPPORTED), never a fabricated evidence ref.
13  3. Per-debater leg classification and a report that REFUSES an unbacked `live` claim.
14
15  The leg vocabulary (`live` / `attempted` / `mock` / `skipped`) and the operator-disposition pin
16  are IMPORTED from `live_flow` rather than redefined – one honesty vocabulary for the phase.
17
18  MOCK-FIRST (§10.4), stated precisely: this module contains no `subprocess` call of its own, but it
19  is not inert – with `DebaterSpec.backend=None` and every live gate passed, `BackendDebater.argue`
20  reaches `ClaudeCliBackend.generate`, which DOES spawn `claude`. What the module guarantees is not
21  "no process ever runs" but "a run that was not live cannot be REPORTED as live":
22  `attempt_live_debate` runs the identical governed path with whatever backend the gates admit, and
23  classifies each leg from counted-call evidence.
24
25  Where that guarantee lives, stated exactly (it is split, and an earlier header got this wrong):
26  `verification_for` / `debater_leg` hold the load-bearing rules – exact CLI class, a checkpoint the
27  CLI reported, and a call spent since this debate bound the backend. `build_debate_report` is the
28  narrower guard: it checks that the `legs` and the checkpoint records AGREE in both directions, and
29  refuses a mismatch. On the `attempt_live_debate` path the two compose; a caller invoking
30  `build_debate_report` directly gets only the agreement check, over whatever it supplies.
31
32  Vendor coupling, stated honestly (invariants 4/20): this module defers its OWN vendor import to
33  function scope (`ClaudeCliBackend` is needed to classify a real CLI backend by TYPE, since an
34  attribute check would be spoofable). That is NOT the same as being vendor-free: it imports
35  `live_flow`, which imports `adapters.frontier.claude_code` at module scope, so importing this
36  module transitively loads the vendor adapter. The lazy import buys locality, not air-gap
37  eligibility – recorded as U36, not claimed away.
38
39  Cost, stated honestly: the per-round charge is a fixed governed UNIT (`round_cost`), not measured
40  provider tokens, so the request declares `usage_units` rather than `tokens` – an immutable
41  record saying `cost_actual: {"tokens": 100}` would misstate what the number is. `cost_actual`
42  bounds the debate deterministically; it is not a metered spend figure. Real provider-token
43  metering is OWED (it needs the CLI to report usage and the backend to surface it), as is the fact
44  that `max_tokens` is accepted and IGNORED by `ClaudeCliBackend` (it emits no output-length flag).

72 |     "dissent", "evidence_map", "cost_actual", "budget", "max_rounds", "legs", "debater_models",
73 |     "debater_notes", "operator_disposition", "mcp_entry",
74 | )
75 |
76 | #: How many trailing transcript rounds a debater is shown. Invariant 8: context is SCOPED, never
77 | #: blanket-forwarded – a round-5 prompt does not carry rounds 1..4 verbatim. One round is what a
78 | #: rebuttal actually needs, and it keeps a live debate at smoke scale ($11 budget discipline).
79 | SCOPED_TRANSCRIPT_ROUNDS = 1
80 |
81 | #: A refusal must be recognizable as "no position was produced" and must never read as an
82 | #: argument. It carries no citations, so the EvidenceManager classifies it UNSUPPORTED.
83 | REFUSAL_PREFIX = "[no position: "
84 |
85 | _DEFAULT_EXCERPT_CHARS = 240
86 |
87 | #: Roles a debate node may hold. The MCP credential is minted from this string, and `gate` /
88 | #: `operator` carry transition authority the debate path has no need of.
89 | #:
90 | #: DEFENCE IN DEPTH, honestly labelled: an earlier comment here justified the whitelist by claiming
91 | #: a `gate`-role debater could promote its own debate output. It could not – `SovereignPolicy`
92 | #: already refuses a gate promoting an entry it authored (invariant 18) and refuses gate
93 | #: self-publication into a promoted state. The whitelist is still worth keeping, because minting an
94 | #: authority-bearing credential for a node that needs none is the wrong default and the guard is one
95 | #: line; but it closes no gap that was open, and reasoning about it later as if it did would be
96 | #: wrong. Fail closed on an unknown role.
97 | _ALLOWED_DEBATE_ROLES = frozenset({"worker", "conductor"})
98 |
99 | #: Bound for DIAGNOSTIC text – backend exception messages (which carry CLI stderr) and
100 | #: dropped-citation notes. `frontier_spawn` sets the precedent in this codebase ("bounded,
101 | #: structured reason – never echo the raw result dict"). Today `ClaudeCliBackend` happens to
102 | #: truncate its own messages, so relying on that would be an inherited accident.
103 | _MAX_RECORDED_DETAIL_CHARS = 200
104 |
105 | #: Bound for the debate POSITION – the largest model-controlled field, and the one that lands in
106 | #: the frozen `debate@1.0` record. Far more generous than the diagnostic bound because this is the
107 | #: argument itself, not a note about it: the prompt asks for one or two sentences, so a position
108 | #: approaching this size is already anomalous. Bounded all the same, because "the model was asked
109 | #: to be brief" is not a length guarantee, and an unbounded field writes straight into an immutable
110 | #: artifact. Truncation is MARKED, so a cut position can never be read as a complete argument.

320
321     The rule itself now lives beside the class it names (`claude_code.is_live_cli_backend`) because
322     `phase-15d.gate` had to apply it at three further sites (U45) and two copies of a honesty rule
323     is one copy too many (the U42 shape).
324
325     It resolves a conductor WRAPPER to the CLI backend it holds, exactly as `verification_for`
326     does. That agreement is load-bearing, not cosmetic: when only verification unwrapped, a
327     wrapper-backed party was classified `leg="mock"` while carrying a populated verification
328     record, so one durable artifact stated both the weaker claim and the stronger one about the
329     same debater. A reviewer found that contradiction; the two now read the same object.
330
331     The import is function-scoped for LOCALITY only – it does NOT make this module vendor-free at
332     module scope (the header records why: `live_flow` pulls the vendor adapter in transitively, U36).
333     """

339     """The verification record backing a `live` claim, or None.
340

```

```

341 | FOUR conditions, ALL required – anything less has been observed to package a non-live run as
342 | `live`:
343 |
344 | 1. the backend IS (or, for a conductor wrapper, directly holds) EXACTLY the real CLI class –
345 | not a subclass, not a duck type (see `_is_vendor_cli_backend`);
346 | 2. a call was SPENT since `calls_before` – a checkpoint with no counted call is contradictory
347 | evidence, and an unreadable counter is no evidence at all; both fail closed;
348 | 3. it carries a non-blank checkpoint STRING that its own `generate` read back out of the CLI's
349 | JSON response (`extract_reported_model`) – a requested `--model` slug never reaches it;
350 | 4. that checkpoint is datable to a call made AFTER `calls_before`, the call count snapshotted
351 | when this debate bound the backend. `reported_model` is never cleared and `calls` is a
352 | LIFETIME counter, so without (4) a backend reused from an earlier debate – every call in
353 | THIS one having failed – still presented a verified checkpoint for a debate in which
354 | nothing succeeded.
355 |
356 | `calls_before=None` means "no snapshot was taken", which cannot satisfy (4) and therefore
357 | cannot yield a verification record. Fail closed: the absence of evidence is not evidence.
358 |
359 | STATED LIMIT, not claimed away (U43). These are instrumentation attributes on an object the
360 | CALLER supplies, and exact-type checking constrains the object's class, NOT its behaviour.
361 | Three deliberate-falsification routes remain and no in-process check can close them:
362 | - forging `reported_model` + `reported_model_at_call` on a genuine backend;
363 | - reassigning `__class__` so a mock reports the real type;
364 | - replacing `generate` on a genuine instance (the type still matches).
365 | What this rules out is every ACCIDENTAL and every mock-SHAPED path – a subclass, a duck type, a
366 | renamed class, a stale checkpoint, an unstamped one. It is NOT a defence against a caller that
367 | sets out to falsify its own evidence. `live` is trustworthy exactly as far as the caller is.
368 |
369 | IMPLEMENTATION (`phase-15d.gate`, U45): the rule now has ONE definition,
370 | `claude_code.verify_reported_checkpoint`, because it had to be applied at three further sites
371 | and a duplicated honesty rule drifts (U42). The conditions above are that function's, in that
372 | order; this module's own suite is the equivalence proof.
373 | """

401 |     """Classify one debater's leg into the shared `live_flow` vocabulary.
402 |
403 |     `calls_before` is the call count snapshotted when this debate bound the backend, so every
404 |     judgement below is about THIS debate rather than the object's lifetime.
405 |
406 |     - real CLI + checkpoint verified for a call in THIS debate -> `live`
407 |     - real CLI + a call spent here (or an unreadable counter) -> `attempted` (never under-reported)
408 |     - real CLI, no call spent here -> `skipped`

```

```

409 |     - anything else, called                 -> `mock`
410 |     - anything else, never called          -> `skipped` (`mock` would overstate)
411 |
412 | A `live` leg additionally requires that a call was actually SPENT here – a verified checkpoint
413 | with no counted call is contradictory evidence (nothing ran, yet something reported), and the
414 | fail-closed reading of a contradiction is the weaker claim.
415 |
416 | That `spent` and `looks` looks redundant – `verification_for` applies the same check internally – and an
417 | earlier version of this docstring asserted it WAS redundant, an equivalent mutant. That was
418 | wrong, and a reviewer refuted it: the two functions read the counter SEPARATELY, so a counter
419 | that advances between the two reads (a concurrent call landing mid-classification) makes them
420 | disagree. The `and` takes the EARLIER, lower reading, which is the fail-closed one. It is
421 | load-bearing, not decorative.

1 | """Governed inter-model flow driven by the LIVE-capable conductor binding – Phase 15D `.flow`.
2 |
3 | Directive §11 track 15D: "conductor decomposes an objective → Scheduler assigns by capability to
4 | live worker nodes → workers publish CANDIDATE artifacts over MCP → gates → conductor SYNTHESIZES
5 | the ACCEPTED set into an acceptance packet."
6 |
7 | This is the Phase-5 end-to-end path (`ConductorPrototype`) driven through the live-capable
8 | conductor binding landed at 15B/15D `.selection`, and it closes the two gaps that path left open:
9 |
10 | 1. **The decomposition drives the task graph and the routing.** `ConductorPrototype` hard-coded
11 |   `t-1`/`t-2` and ignored the backend's `proposed_tasks`. Here the conductor's own
12 |   decomposition becomes the task graph and its declared ordering – fail closed: an element that
13 |   does not name a KNOWN capability with a real description is REFUSED and recorded, never
14 |   defaulted (a guessed capability would route work by inference, and the Scheduler must route
15 |   by descriptor – invariant 4). NOT yet consumed: each worker is still handed the OBJECTIVE
16 |   entry as its context ref, not a per-task scoped entry carrying the subtask description, so
17 |   the artifacts differ only by task id. Delivering per-task context is owed (U35) – the graph,
18 |   the ordering and the routing are real; the work content is not yet task-specific.
19 | 2. **The gates are the real gate engine.** `ConductorPrototype` promoted artifacts with a raw MCP
20 |   `transition` (a stand-in). Here `GateEngine.evaluate` produces a `gate@1.0` verdict and
21 |   `apply_to_task` drives the task graph, and ONLY a PASS verdict is followed by the MCP
22 |   promotion – a failed artifact cannot advance (invariant 16), and the promoting client is the
23 |   GATE node, never the author (invariant 18).
24 |
25 | Honesty (directive §6 / §10.4): every run declares its LEGS. The CONDUCTOR leg may be called
26 | `live` only when the executing checkpoint was VERIFIED – i.e. reported back by the CLI itself
27 | (`reported_model` → `bind_conductor_selection`). `build_acceptance_packet` REFUSES to package a
28 | mock run as live, so a substituted result cannot be presented as a real-provider result by
29 | construction rather than by convention. No OTHER leg carries a verification record yet, so for
30 | those `live` is refused outright rather than merely unchecked – a live worker path must arrive
31 | together with its own evidence record. `attempt_live_flow` runs the whole flow through the
32 | governed live-spawn gates and degrades to skip-with-record on any unmet gate, making no live
33 | call; a run that reached the model but did not complete is reported `attempted`, never `skipped`.
34 |
35 | The conductor SELECTION (fable-5, operator-selected) and the EXECUTING checkpoint stay separate
36 | records throughout (directive §11 15D; `control_plane.conductor.selection`).

1359 |
1360 |     Phase 17B `legs` (directive $16, closing the worker half of U58). This is the worker mirror of

```

```

1361 | `live_conductor_handle`: the node is born from `spawn_claude_code_terminal` – the ONE governed
1362 | live-frontier spawn site – so every gate applies before any live call (roster profile +
1363 | LIVE_OPERATION_AUTHORIZED, provider-live, R8 §6 operator terms, CLI presence, I-X3 acquire), and
1364 | it raises through to the caller when a gate is unmet rather than degrading silently.
1365 |
1366 | The handle carries its own verification closure: `calls_before` is snapshotted at BIND time, so
1367 | the checkpoint the CLI reports back is datable to a call this flow spent (U45's rule, applied to
1368 | the worker path). Without that record `derive_worker_legs` cannot produce a `live` worker leg –
1369 | the claim is unrepresentable, not merely unchecked.
1370 |
1371 | `release` gives the I-X3 terminal back; `LiveGovernedFlow.close` calls it (D-LOOP-1).

1 | """Phase 15D `.succession` – LIVE conductor succession over a governed run.
2 |
3 | Directive §11 track 15D, the fourth sub-step: **kill the conductor mid-run, resume on a DIFFERENT
4 | backend, prove ZERO LOSS, then restore the operator selection.** Invariant 28 ("conductor
5 | succession works: serialize to MCP, Resume→Select") is the claim under test; invariant 5 ("project
6 | state lives outside model context") is *why* it can hold at all.
7 |
8 | WHAT THIS MODULE DOES NOT DO: it does not reimplement succession. `SuccessionManager`
9 | (`control_plane/recovery/succession.py`, gated at Phase 11) owns serialization, the §19.1 staleness
10 | checklist and the I-X3 handoff; `LiveGovernedFlow` (gated at `.flow`) owns the governed loop;
11 | `control_plane/conductor/selection.py` (gated at `.selection`) owns the selection records. This
12 | module composes those three across one interrupted run and decides – fail closed – whether the
13 | resulting evidence supports the claim "the conductor was replaced and nothing was lost".
14 |
15 | THE KILL IS AT A GOVERNED BOUNDARY, AND WHAT IT REPLACES IS THE CONDUCTOR – NOT THE RUN. The
16 | predecessor is interrupted BETWEEN scheduling waves, with the completed waves' artifacts already
17 | gated and promoted in MCP: its adapter is closed (releasing its subscription terminal), its MCP
18 | client is closed, and the successor is a separately-constructed adapter, on its own MCP session and
19 | node_id, that reloads all 12 conductor files FROM MCP.
20 |
21 | Be precise about the scope of that claim, because an earlier draft of this module overstated it.
22 | What is replaced is the CONDUCTOR (adapter + backend + MCP session). What deliberately SURVIVES
23 | in-process is the orchestration harness: the `LiveGovernedFlow`, its `TaskGraph`, `Scheduler`,
24 | `CapabilityRegistry`, the worker adapters and the `_RunState`. That is the design – a successor
25 | takes over the SAME governed run (invariant 28 / I-CN1) rather than starting a new one – but it
26 | means this unit does NOT demonstrate that conductor-side orchestration state is MCP-resident and
27 | rebuildable. See U48.
28 |
29 | HONESTY RULES (directive §6/§10.4), each pinned by a test:
30 | - `zero_loss.ok` is UNREACHABLE with an empty pre-kill accepted set, AND the durable claim
31 |   additionally requires the accepted set to have GROWN across the succession (`work_advanced`) –
32 |   otherwise a "succession" that resumed nothing would earn the claim by preserving the 12
33 |   read-only conductor files that bootstrap publishes as ACCEPTED. See U49.
34 | - artifacts are compared by CONTENT HASH read back from MCP, not by entry id: an id that
35 |   survives while its bytes changed is loss, not preservation. This is the LOAD-BEARING half of
36 |   the comparison. The `task_states` half is weaker by construction and is labelled as such
37 |   (U48): both sides read the surviving in-process graph, so it cannot detect graph loss.
38 | - "resume on a DIFFERENT backend" is a LABEL-DIFFERENCE REFUSAL, not structural proof. It
39 |   catches the degenerate identical-configuration case and nothing more. `capability().adapter`
40 |   is hard-coded to `conductor_fable5` for every `ConductorAdapter`, so it never discriminates;
41 |   the discrimination rests entirely on `model_name`, which this module ASSIGNS onto the backend
42 |   object. Two identical `MockReasoningBackend` instances can satisfy it. See U50.
43 | - the kill is REFUSED, not merely recorded: if the predecessor is still `is_active` after
44 |   `close()`, the succession is abandoned rather than reported. A recorded-but-unchecked death
45 |   field is not a guard.
46 | - the §19.1 staleness checklist GATES the successor: a failed checklist stops the run before the
47 |   successor assigns any work.
48 | - leg vocabulary is IMPORTED from `live_flow`/`live_debate`, never redeclared, and a `live` leg
49 |   with no verification record is unrepresentable. The classifier used here is the HARDENED one
50 |   from `live_debate` (exact type + freshness against a bind-time call snapshot); `live_flow`'s
51 |   weaker `_leg_for_backend` is U45, unified at `.gate`.
52 | - the run-level spend leg merges UPWARD across both conductors: a succession must not let the
53 |   predecessor's spend disappear from the record.
54 |
55 | MOCK-FIRST, AND THIS UNIT HAS NO LIVE PATH AT ALL. Nothing here spawns a provider CLI, and unlike
56 | `live_flow.attempt_live_flow` / `live_debate.attempt_live_debate` there is no `attempt_live_*`
57 | entry point, no `LiveAuthorization` check and no supervised live spawn. A live succession is OWED
58 | (U51); it is not merely un-run. The public `mock_*_handle` helpers hard-code `leg="mock"`, so they
59 | must NOT be handed a real vendor backend – that would under-report a real subscription spend.
60 |
61 | STATED LIMITS, recorded in docs/registers/UNRESOLVED_ISSUE_REGISTER.md (U46–U53).

175 |     finished. Both sides are read back from MCP (see `capture_project_snapshot`), never taken from
176 |     a node's own report of what it produced (I-M1).
177 |
178 |     `before`/`after` are `{ "accepted": {entry_id: content_hash}, "task_states": {task_id: state} }`.
179 |
180 |     A verdict of `ok=True` requires that the pre-kill accepted set was NON-EMPTY. This is the
181 |     anti-vacuity rule: every preservation check below is a universally-quantified statement over
182 |     that set, and all of them hold trivially when it is empty. A succession that happened before
183 |     any artifact existed put nothing at risk and therefore proves nothing about loss.
184 |
185 |     That rule alone is WEAK in practice, and saying so is the point of `work_advanced`: bootstrap
186 |     publishes the 12 conductor files as ACCEPTED, so a real run's pre-kill set is never empty and
187 |     the emptiness guard can only fire against a project this runner cannot construct. `ok` on its
188 |     own is therefore satisfiable by preserving 12 read-only files. `work_advanced` records whether
189 |     the accepted set actually GREW across the succession – i.e. whether the successor completed
190 |     work the predecessor never saw – and the durable claim in `publish_and_gate_report` requires
191 |     BOTH. `ok` keeps its literal meaning (nothing was lost); `work_advanced` supplies the
192 |     non-vacuity the emptiness guard cannot. See U49.
193 |
194 |     NOTE on `task_states` (U48): both sides are read from the surviving in-process `TaskGraph`, so
195 |     `tasks_preserved`/`done_tasks_preserved` compare that object against itself and cannot detect
196 |     graph loss. They are retained as regression detectors for the successor's own wave execution,
197 |     NOT as evidence of MCP-resident state. The load-bearing evidence is the content-hash half.

1  """Operator command surface – the objective intake + the unified approval queue (Phase 15E `.objective` ).
2
3  Directive OP-7 §12.5 item 5 (a plan §10.3 requirement, a 15E exit criterion): *an objective input
4  (operator types an objective → conductor decomposes → plan surfaces for approval) and the
5  approval-queue drawer (plan gates, protected actions, clarifications, badge count). Without this the
6  conductor cannot receive work or ask the operator anything.* OP-8 §13 reframed the objective input:
7  the operator drives a live conductor pane rather than a batch form – but the governed **pause for
8  operator authority** it describes (a proposed plan surfaces, protected actions queue, clarifications
9  surface, all with a badge count) is exactly this surface. This module is that governed pause, not a
10 new authority: it COMPOSES the pieces already built and re-implements no authority, gate, classifier
11 or lifecycle (the one re-derivation is a display-only protected/destructive LABEL, read from the
12 broker's own frozensets – never a re-classification).
13
14 * The **decomposition** and the **plan gate** are `LiveGovernedFlow.begin` (Phase 15D `.flow` ):
15   the conductor proposes tasks, the REAL gate engine renders a `gate@1.0` plan verdict. This module
16   reads that verdict; it never re-decides it.
17 * The **protected/destructive/clarify** classification is the `CommandBroker` (Phase 12 voice): a
18   proposed command is queued for the operator, never auto-run. This module MIRRORS a broker outcome
19   into the one drawer and routes the operator's decision back to the broker – it does not
20   re-classify a verb.
21 * The **authority** is invariant 1: only the operator may resolve a queued item. That is enforced
22   here in code (an `Identity` whose role is not "operator" is refused), not by convention.
23
24 Two load-bearing governance properties this surface adds, both fail-closed:
25
26 1. **The plan pauses for the operator BEFORE assignment (invariant 1).** `ObjectiveIntake.submit`
27   decomposes and gates the plan, then STOPS: no worker is assigned until the operator approves the
28   queued plan item. The conductor proposes; the operator disposes.
29 2. **A gate-failed plan is NOT operator-approvable (invariant 16).** A plan whose `gate@1.0` verdict
30   did not pass is enqueued `approvable=False`; `resolve(decision="approve")` on it is refused. The
31   operator holds final authority, but final authority is not an override of a failed gate – there
32   is no override path (invariant 16). The operator may only dismiss (reject) such a plan.

1  """The operator's approval drawer, rebuilt from REAL SESSION EVENTS – Phase 17D `.events` (OP-11 §16).
2
3  **The defect this replaces (operator finding F2, 2026-07-25).** The operator opened the shipped shell
4  and found three pending approvals waiting for them: a plan, a protected action, a clarification. No
5  session had produced any of them. They were Phase 16D's DETERMINISTIC DEMONSTRATION trio – a canned
6  objective run through the real flow, two canned commands run through the real broker – rebuilt
7  identically on every fetch. The authority path was real; the content was canned. A queue that shows
8  work nobody asked for is worse than an empty one: it teaches the operator to dismiss their own
9  drawer.
10
11  This module is the replacement producer. The drawer is a FOLD over the append-only log of events the
12  running session actually produced (`apps/desktop/approvals/session-events.js` writes it). **An empty
13  session shows an empty drawer.** There is no path here that invents a row.
14
15  WHICH PRODUCERS ARE WIRED TODAY, exactly (invariant 3 – the directive names three; the shell has
16  one). The `voice:capture` path records: a protected/destructive verb the CommandBroker queued, and a
17  clarification the bridge would not route. NOT wired: a protected verb TYPED at the conductor pane
18  (those keystrokes go straight to the ConPTY and never reach the broker – U149), and a gate promotion
19  from a governed dispatch (`recordDispatchPlan` exists and is covered, but its only caller would be an
20  operator-driven dispatch, which lands with the conductor conversation, 17E/OP-8 §13; the launch-time
21  demonstration dispatch is deliberately not recorded – it would be finding F2 one layer down). The
22  `plan` event kind below is therefore built and tested ahead of its producer.
23
24  WHY THE LOG IS NOT TRUSTED, AND WHAT THAT BUYS. The log is written by the shell – the least-trusted
25  surface (invariant 29). So a recorded event is treated as a CLAIM about what happened, and everything
26  that decides how it appears to the operator is re-derived here, by the same authorities that decided
27  it the first time:
28
29  * an `utterance` event is re-routed through the REAL `ConductorVoiceBridge` router over the REAL
30  `CommandBroker` (invariant 30 – this module owns no classifier). The recorded classification must
31  match what the classifier says now, or the whole feed fails closed. So the shell cannot promote an
32  ordinary sentence into a protected-action row, cannot demote a protected verb into a dismissible
33  question, and cannot mint a row with no utterance behind it. The chat sink handed to that router
34  REFUSES delivery: re-deriving a recorded event must never speak to the conductor;
35  * a `plan` event's approvability is DERIVED from its recorded `gate@1.0` verdict through the same
36  `propose_plan_for_approval`/`build_plan_proposal` the 15E surface uses, and the record must
37  validate against the frozen `gate@1.0` schema and carry `decided_by: "gate_engine"` – so a
38  hand-rolled `{"verdict": "PASS"}` is refused, and an approvable plan at least has the shape of a
39  rendered verdict (invariant 16 then governs what may be done with it: no override);
40  * a `decision` event is replayed through `ApprovalQueue.resolve`, so operator-only authority
41  (invariant 1) and the no-approve-of-a-failed-gate rule (invariant 16) are re-enforced on EVERY
42  rebuild. That is also what makes the operator's decisions PERSIST across fetches – the gap 16D
43  recorded as owed – without any component keeping a mutable queue alive.
44
45  HONEST RESIDUAL (invariant 3), stated at its full width because two reviews measured it. Re-derivation
46  binds the drawer to the real classifiers; it is NOT proof that a recorded event was emitted by a
47  governed producer. Concretely, a shell process (or anything that can write the log file) can still:
48  * INJECT a row, by writing a *plausible* utterance ("spawn a worker") that the real classifier does
49  accept, or a FULLY-FORMED `gate@1.0` record carrying `decided_by: "gate_engine"` – the checks
50  above refuse malformed forgeries, not well-made ones (`U205`);
51  * DISPOSE of a row, by writing a `decision` event: the replay re-enforces invariant 1 and 16 on it,
52  so it can never approve what is not approvable and never resolve as a non-operator, but an
53  APPROVABLE item can be recorded as decided and will stop appearing in the operator's drawer
54  (`U206`). This is the authority-adjacent half, and it is the one the shell's own shape checks
55  (`recordGovernedDecision`) do NOT close – those bind the shell's honest paths, not a tampered file.
56  This is a narrower surface than the trio it replaces (every row now corresponds to something a real
57  classifier accepts, and every decision is re-governed), and it is bounded by the integrity of the
58  shell process and its per-run file, which the supervisor already owns. The unforgeable binding – a
59  producer-minted stamp the drawer builder verifies – is owed, registered, and not claimed here.
60
61  PURE + FAIL-CLOSED: no I/O beyond reading the log the caller names, no model call, no credential, no
62  network, NO MCP server. Any malformed event, any classification mismatch, any refused replay the
63  UNAVAILABLE feed (`sourced:false`, the reason named, an EMPTY drawer) – never a partial drawer and
64  never a fabricated row.

1 | """Sovereign authorization policy – THE authority (Plan section 3.2; invariants 7, 10, 13).
2 |
3 | This is deliberately OUTSIDE mcp_server/: MCP is access/transport, not authority (I-M2).
4 | The MCP server authenticates a node's identity and then asks this policy for a verdict on
5 | every write. Deny-by-default. All role/scope decisions live here and nowhere else:
6 |
7 | - workers publish CANDIDATE only, and may move only their OWN entries to UNDER_REVIEW;
8 | - promotion to ACCEPTED*/REJECTED is reserved to the gate engine and the operator
9 |   (I-M6: no worker self-canonization);
10 | - the canonical directive (kind=directive) and conductor files (kind=conductor_file)
11 |   are not worker-writable (Plan Phase 3A exit criterion);
12 | - reads are project-scoped; candidate vs accepted are distinct read scopes.
13 |
14 | The collaboration surface at the bottom of this module (tasks, node-to-node messages,
15 | bounded debates, candidates, synthesis) was added at Phase 19 unit 2 (U326). Those decisions
16 | had been made inline inside `mcp_server/collaboration_service.py` – a second, divergent copy
17 | of the authority in the one package invariant 7 names. The directive named twelve; the file
18 | carried FIFTEEN of that class: fourteen moved here and the fifteenth (`update_task`'s owner clause)
19 | was deleted as provably dead, its entry point returning the read verdict (U343). They are
20 | relocated, and THREE of the surviving rules are
21 | also changed – measured scenario by scenario, never asserted ($2 of
22 | `docs/evidence/PHASE19_UNIT2_U326_POLICY_DELEGATION_CHECKPOINT.md`, 19 of 34 scenarios differ):
23 | `voice` joined `_SCOPED_ROLES`, so a voice identity can no longer read or cancel any task in the
24 | project; a `gate` node may now open a debate, because `authorize_debate` is the canonical I-DS1
25 | rule and the inline copy was stricter (a directed widening, recorded in U349); and a malformed
26 | role is refused where the inline copy served it. Beyond those three the RULES are the ones the
27 | service already raised; $2's remaining deltas are what a caller is TOLD, not what it may do –
28 | including a `voice` caller's `open_debate` refusal, which now reads as the canonical rule's own
29 | sentence. There is no second copy of these rules left to edit – though a DELETED call site in
30 | `mcp_server/` still moves a verdict without touching this file, which is what the harness's Group C
31 | rows exist to catch.

307 |     accumulated stall timers, and the task's synthesis gate was blocked behind a node that
308 |     would never answer).
309 |
310 |     This is a ROLE rule, not a participation rule, and the distinction matters more than the
311 |     first draft of this docstring admitted (19.5 spec-auditor MAJOR-1). It refuses every
312 |     worker and voice identity, including the participants a debate is most likely to stall
313 |     between – but it does NOT refuse a DIRECTING node that is itself a participant, and the
314 |     conductor usually is one: `_task_participants` includes the task's creator, so a debate
315 |     opened between the conductor and a worker admits the conductor here on role alone. A
316 |     conductor can therefore abort a deliberation it is arguing in, which is **U350's** open
317 |     question (recorded there for `authorize_debate_close`, whose shape this copies) and not a
318 |     protection this rule provides. `test_the_conductor_may_abort_a_debate_it_is_arguing_in`
319 |     and the verdict matrix's `abort_own_debate` column pin that as the CURRENT behaviour, so
320 |     U350's eventual answer moves a cell rather than passing unnoticed.
321 |
322 |     Why role and not participation, given that: a rule refusing every participant would put
323 |     the stall back. The conductor is frequently a participant, and if it could not abort, the
324 |     debate it opened with a dead worker would be permanent again – the exact defect. The
325 |     operator is admitted here too, on role alone (`operator | abort_fresh_debate` reads 'ok'
326 |     in the verdict matrix). That is all this module decides. WHICH identities any surface
327 |     actually mints, and what recourse exists when the conductor's own pane dies, are
328 |     questions about the product and not about this rule – asked and answered on the evidence
329 |     in **U420**, where two successive drafts of this docstring answered them here and were
330 |     wrong in opposite directions (19.5 spec-auditor rounds 2 and 3). An authority module
331 |     states its verdicts.
332 |
333 |     What keeps an abort from being a gate override is downstream, not here: ABORTED is not
334 |     CLOSED, and the store reports the two separately (no UI renders that distinction yet –
335 |     **U412**, owned by 19.8). The synthesis gate that refuses to
336 |     count it lives on the `sovereign_tools` tool path – `CollaborationService.record_synthesis`
337 |     has no debate check of its own (**U410**), so that defence is as wide as the product's
338 |     single caller, not as wide as this module.

```

1 | """LIVE_OPERATION_AUTHORIZED – the enforced, fail-closed gate that must exist BEFORE any
2 | live frontier path (directive §10.1 / §11; register OP-4/OP-5 → **OP-6**; Phase 15A `.liveauth`)).
3 |
4 | Rationale (directive §10.1): for the entire staged build the frontier adapters ran in mock
5 | mode, so "live operation" was impossible simply because no live path existed –
6 | enforcement-by-absence. The moment a live adapter is wired that natural barrier is gone, so
7 | an EXPLICIT authorization must already fence it. This module is that fence: no live call is
8 | made here.
9 |
10 | Phase-15 rewrite (register **OP-6**, 2026-07-19): the operator authorized live multi-model
11 | orchestration across **two** providers under their existing subscriptions and raised the
12 | concurrency allowance to **2 terminals per subscription** by explicit direction (I-X3 was
13 | formally verified-at-1; the raise is operator-ordered, governor-capped, reversible). The
14 | scope this module pins therefore moves from `{provider: claude_code, terminals: 1}` (OP-4)
15 | to `{providers: [claude_code, openai_codex_cli], terminals_per_subscription: 2}` (OP-6).
16 |
17 | Phase-18B extension (register **OP-12**, 2026-07-31; directive §17): the operator authorized
18 | two FURTHER live frontier providers – `grok_build` (CLI `grok`) and `google_antigravity`
19 | (CLI `agy`) – each with its own subscription resource at **allowance 1**, never merged with
20 | the other and never merged with the OP-6 pair (operator directive §12). Because the scope is
21 | code-pinned, that authorization had to be written HERE before the operator's own live switch
22 | could name either provider: U237 recorded that the previously-published instruction ("extend
23 | `config/live_operation.json`") was impossible against the OP-6-pinned loader, which raised on
24 | any other id and would have denied `claude_code` too. This module is that missing extension.
25 |
26 | Provider identity for the OP-6 pair is the **frozen `node.schema.json` adapter enum**
27 | (schemas/ is the single source of truth): `claude_code` and `openai_codex_cli`. The
28 | operator/directive shorthand "codex" is accepted as an alias and normalized to the canonical
29 | schema id, so `assert_provider_live(cap.adapter)` – called by the profile loader and the
30 | supervised spawn path with the schema enum value – works directly.
31 |
32 | **U227, and its resolution – stated rather than papered over.** Through 18B/18C: node@1.0's
33 | `adapter` enum had NO member for either OP-12 provider, the enum is frozen (Phase-0 manifest)
34 | *and* pinned by Architecture Plan §9.1, so neither this module nor any other could add one, and
35 | a schema-valid node RECORD naming either provider was impossible. **The operator ruled on
36 | 2026-08-01 (OP-12.1, directive §17.1): by SUCCESSOR SCHEMA** – `schemas/node.schema@1.1.json`
37 | admits both ids (and `ollama_local`, U254) while `@1.0` and Plan §9.1 stay untouched, which is
38 | why directive §17's untouchable set is honoured rather than routed around. Nothing here ever
39 | fabricated a false member, and nothing here changes with the ruling: **the ids in this module are
40 | still product-layer authorization scope, and admitting a vocabulary is not authorizing a call.**
41 | Live scope is what this file decides, and only the operator's config plus the pinned rows below
42 | decide it.
43 |
44 | Scope is fixed by the operator ruling, not by the config file. The config names ONE
45 | authorizing register row and gets exactly that row's provider set:
46 | - **OP-6** -> {claude_code, openai_codex_cli} (unchanged, operator-reaffirmed)
47 | - **OP-12** -> the OP-6 pair PLUS {grok_build, google_antigravity}
48 | A provider outside the cited row's set is refused – a config can neither widen a row nor
49 | borrow another row's scope, and a provider no row authorizes needs a NEW operator ruling.
50 | Terminals: at most **2** per subscription globally (a config may narrow to 1, never widen),
51 | and each provider is further capped by its own code-pinned allowance – 1 for both OP-12
52 | providers, so an operator config that says 2 still yields 1 for those two.
53 |
54 | Fail-closed everywhere: absence -> DENIED (not authorized); malformed / out-of-scope ->
55 | raise (never silently authorize, never silently downgrade to permit; never WIDEN beyond the
56 | code-pinned scope). Deterministic permission logic – never model output (Buildout Directive §4).

1  """Scoped context compiler (Plan §7-P9; invariant 8).
2
3  Assembles the context a node receives for a task by role + task + NEED-TO-KNOW – never a
4  default full-transcript forward. For a task it includes only:
5  - the task objective (the scoped directive for THIS task);
6  - the ACCEPTED outputs of the task's DIRECT dependencies (what the worker must build on);
7  - the node's role scope (its constitution/directive);
8  - explicitly requested evidence refs.
9  It excludes: sibling tasks' work, candidates still under review, superseded/rejected entries,
10 and the project's full history. All reads go through MCP (governed, provenance-bearing).
11
12 The naive baseline (`compile_naive`) forwards the whole shared transcript – the compiler's
13 job is to beat it measurably (token_meter), and a test asserts the scoped bundle contains
14 ONLY the need-to-know entries.

> TION AT ENTRY: tags were truth and state AGREED with them (newest gate/phase-17b, no gate/phase-17c, next_step already phase-17c.receipt), so no reconciliation commit was owed
> - but HEAD was THREE commits ahead of state.last_commit (0f106bc -> f9dc5e5): iteration 97's first turn landed c0c2168 (the U177 channel sweep), e2ad150 (launcher budget) and f
> 9dc5e5 (the review fixes) and then ended before writing evidence, leaving the regenerated @1.4 receipt and the register rows uncommitted in the tree. Those were the unit's inpu
> ts, not new work. THIS UNIT ADDED NO PRODUCT CODE, deliberately and for the third time in this phase: a fix applied after validation voids the falsifications the validation res
> ts on. WHAT WAS VERIFIED FIRST: the receipt is exact-source (source.commit == HEAD f9dc5e5, tracked_product_tree_clean, taken 7 s after that commit, ok true, failed_checks empty
> y, 59/59 legs) against a LIVE fable-5 conductor - real PCM -> real WSL Parakeet (41.7 s transcribe, mock:false) -> bridge -> the live session, which answered; armed-before-the-
> model; a real PreToolUse DENIED by the supervisor through the pinned hook while armed and again after the sweep; audio discarded; no TTS; protected verb queued not delivered; U
> 178's ended-turn-still-denies leg; two live exchanges, torn down in-unit (D-LOOP-1 satisfied: session killed, lease 1->0, scratch pane and ledger gone). U177's runtime half: 24
> /24 renderer channels driven at an ADMITTED turn, uncovered/missing/undriven all empty, survival read from the authority's own snapshot, restriction still ENFORCED afterwards.
> SUITES (foreground, mine): desktop 563 (was 543), terminal 209, py -3.12 pytest 1441 in 369.59 s; both mutation harnesses ALL CAUGHT with byte-identical restoration and no resi
> due; frozen manifest --check no drift. BOTH MANDATORY REVIEWERS RAN FOREGROUND ON f9dc5e5 AND BOTH SAID NOT YET: gate-validator PASS_WITH_RESERVATIONS with a BLOCKING precondition
> ion (no evidence-report section for this unit, and 11.7's standing last word literally said 'the gate does not close here') + 1 MAJOR + 8 MINOR; spec-auditor PROHIBITED DRIFT:
> NONE but 'do not tag as it stands' on evidence honesty, 4 MAJOR + 8 MINOR. The validator re-ran every suite and both harnesses itself and reproduced the numbers. THE REMEDIATIO
> N THEY BOTH PRESCRIBED WAS DOCS-ONLY, WHICH IS WHY THE RECEIPT IS STILL EXACT-SOURCE AND NO SECOND LIVE EXCHANGE WAS SPENT: section 12 of PHASE17C_EVIDENCE_REPORT.md supersedin
> g 11.7 (including, in the report rather than buried, the @1.3 run that FAILED review because the sweep prepended its probe string to a prompt the operator never composed, in th
> e vendor's durable session store); U189 rewritten AFTER the verdicts came back because its draft asserted the review in the past tense while it was in flight; U191 rewritten on
> all three counts the auditor found (RECOVERY_DIR is the wrong bound - the approval queue is ephemeral for everyone and the real trip-wire is 16F's shared queue landing; 'queue
> s a real proposal' overstated an emitter that persists nothing; 'cannot be fixed with a flag' was a false dichotomy since main knows SHELL_SELFCHECK from its own environment).
> Both were UNCOMMITTED drafts, so nothing committed was rewritten - append-only holds. U192-U204 opened with owners for every carried finding; none is fail-open in shipped autho
> rity logic. U199 got a MEASUREMENT instead of a paragraph: one governed emitter round trip is ~0.96-1.01 s on this host (4 runs) against a 4.08 s sweep window, so the window do
> es not fit six - which emitter-backed channels really round-tripped is unknown from this receipt and is now recorded as unknown; the sweep's load-bearing property is unaffected
> because it is read from the authority's state, not the rows. NOT a directive section 8 BLOCKED condition. Status RUNNING, consecutive_failures 0. NEXT UNIT phase-17d: the appr
> oval drawer must source ONLY real session events (the deterministic ap-1/ap-2/ap-3 demo trio becomes test-only, operator finding F2), guard pane:resize for sessionless panes (U
> 73), discharge U69 via the assembled typed path, and fix the non-hermetic wsl-PATH test (audit R4, monkeypatch shutil.which). Then 17E is the last track: the assembled in-Elect
> ron receipt, FINAL report addendum, product/fully-live, and the operator is addressed once.",
9 |     "2026-07-31 iter96: phase-17c.disarm-authority CHECKPOINT, NO TAG. RECONCILIATION AT ENTRY: tags and state AGREED (newest gate/phase-17b, no gate/phase-17c; next_step alrea
> dy phase-17c.disarm-authority, last_commit 73b12e0, HEAD 200ec52 the iteration-95 state commit), so no reconciliation commit was owed. THE UNIT: steps (1)-(2) of the batch iter
> ation 95 handed me -- fix U178 first, then U179-U186 -- test-first, all eight new authority tests RED before a line of product code moved. U178 IS THE POINT AND IT WAS AN INVAR
> IANT NEGATION, not a limit: disarm() cleared_active on any keyDown while the model was still generating the answer to the SPOKEN prompt, so that turn's tool calls stopped bein
> g denied (I-V3/invariant 25 negated by the fix for U166). A disarmed ACTIVE turn now moves to a terminal 'ended' state that keeps denying PreToolUse/PermissionRequest for that
> turn id; the bound is the operator's NEXT PROMPT, which is the safe forgery direction (a forged UserPromptsSubmit lifts a restriction the operator had ALREADY ended, while the r
> estriction on the child's own ACTIVE turn stays unreachable from that socket). A disarmed PENDING turn ends outright -- nothing was ever presented to the model. U166 intact: th
> e operator's typing is admitted. AND THE OPERATOR CAN SEE IT: turnState() splits 'restricted' (a turn holds this session against you -- false after your keystroke) from 'tools_
> denied' (a denial is still running), and the chrome gains a third 'ended' state rather than going blank, because a blank badge reports a live denial as OVER, the understating d
> irection. ALSO CLOSED, each falsified: U176 (stop()) releases through reset() with supervisor_authority_stopped provenance -- the one release path that wrote no voice_turn_* row
> ); U180 (admitted -> vendor_reported_submission end to end, badge reads 'Delivered to conductor (CLI reported)', because the child holds both the payload and the bearer so admi
> ssion is its claim about itself); U181 (the hook AND the module it requires -- both inside the conductor's writable cwd -- are re-hashed at EVERY dispatch and fail closed, pinn
> ed at launch against the ticket's own hash, cleared at session exit; new voice/policy-bytes.js over injected I/O; NOT confinement, U25 still owns that); U182 (2000-row audit ri
> ng with a drop count, bounded fate map, turnFate reads the state machine instead of deep-copying a child-floodable array every 120 ms); U183 (session-id mismatch recorded again
> st the ADMITTED id); U184 (the header says the child cannot SYNTHESIZE the keystroke and admits it can ELICIT one); U185 (the second fixture caller gets the SHELL_SELFCHECK gua
> rd, asserted as a PROPERTY over every caller); U186 (the desktop suite now goes red when main.js and PINNED_BASELINE disagree, with the recovery procedure in the assertion -- i
> t failed exactly that way in this unit before the harness was re-run, which is the only demonstration that matters; every harness has an npm script). TWO REFUSALS RECORDED AS R
> EFUSALS RATHER THAN DELIVERED AS FIXES: U183's literal ask (compare against conductorLaunch.sessionId) is a DIFFERENT NAMESPACE -- main's lease key pane-1#<pid>.<seq> vs the ve
> ndor CLI's own session id -- and would report a mismatch on every healthy event; and U179's fix does NOT make the pane's self-reported mode true. No launch record can: build_in

```

```
> teractive_command emits --model and nothing about permission mode (checked, not assumed), and setting the flag false would refuse EVERY delivery on this host, whose live pane r
> eally does show 'manual mode on' -- visible in PHASE17C_CLOSE_SELFCHECK.json's own write.pane_state.evidence. So the acceptance is conditioned on a live supervisor-owned bounda
> ry RE-READ at the pane read (the service stopping between guard 1 and guard 3 now refuses), which bounds the damage of a wrong reading without pretending it is verified; the re
> mainder is U188, open, owned. FALSIFICATIONS: new tools/mutation/disarm_authority_mutations.js -- 11 mutations, ALL CAUGHT, every touched file restored byte-identically (turn-a

> also removes a latent AttributeError - ConductorAdapter.export_session_state reads self._backend.calls unconditionally and ClaudeCliBackend had no counter). PROVENANCE (recorde
> d deviation): iter 43 crashed mid-unit (D-LOOP-1); tracked changes were stashed, untracked new files survived. LOOP_STATE said 'redo clean'; the recovered material was instead
> INSPECTED (coherent; all dependencies - read_accepted/publish_acceptance_packet/reported_model and conductor_spawn's exact signature - matched committed code), restored and RE-
> GATED here rather than trusted or deleted unexamined. TWO REAL DEFECTS found in it, test-first, both proven load-bearing by mutation: (A) decompose_plan discarded the conductor
> 's declared deps (always {}), so the plan gate's plan_acyclic criterion evaluated an EMPTY graph and passed vacuously -> _resolve_deps maps 1-based PROPOSED indices to ASSIGNED
> task ids (ids number only accepted tasks), fail closed on non-int/bool/out-of-range/forward/self/refused-prerequisite, each refused WITH ITS SPECIFIC REASON and cascading (bac
> kward-only edges also satisfy add_task's define-deps-first precondition and make a cycle structurally impossible from this path; plan_acyclic stays an independent check); (B) r

```

```

> un() scheduled exactly ONE wave, so every dependent task was silently never executed, never gated, absent from BOTH the accepted and failed sets -> waves run to quiescence, bou
> nded by _max_waves. 17 findings fixed pre-commit incl. 5 MAJOR: legs reported 'skipped' where a call was already COUNTED (-> ATTEMPTED_LEG derived from counted-call evidence);
> the mock handle advertised the claude_code VENDOR descriptor (frontier/subscription_backed) for a MockReasoningBackend run (inv 3 -> neutral_mock_conductor_descriptor); leg ho
> nesty enforced for the conductor leg ONLY while the docstring claimed the general rule (-> live/attempted UNREPRESENTABLE for any other leg); an unverified live reply DESTROYED
> an entire governed run whose artifacts were already gated/promoted in MCP (-> leg DEGRADES live->attempted, packet still published: report less, never discard the record); the
> gate-promoted operator-facing packet had NO field distinguishing gate promotion from operator acceptance (inv 1 -> operator_disposition:'pending' pinned in ACCEPTANCE_PACKET_K
> EYS). Also inv 13: the CAS applied:False/conflict report from a lost promotion was discarded and the entry counted accepted -> now an EXPLICIT conflict object, entry excluded,
> task graph deliberately NOT forced backwards (DONE->BLOCKED is forbidden by the state machine, itself inv 16). Node-local refusal reasons carried BESIDE the gate record, never
> grafted onto it (gate@1.0 is frozen additionalProperties:false - grafting made it schema-INVALID; overwriting 'reasons' misattributed node text to decided_by:gate_engine) + a n
> ew test validates EVERY gate record the flow emits against the frozen schema. THREE findings were against MY OWN TESTS (two tautological assertions, one name stronger than what
> it pinned) - rewritten, not argued away. NO live call (R8 s6 [OPERATOR] live-terms cannot be self-discharged, s10.4; validator ran the suite under a global subprocess ban: 0 s
> ubprocesses from this unit's 81 tests); NO credential handling (s2.2 - module imports no os/subprocess/socket/urllib, calls no open()); config/live_operation.json NOT written (
> mtime+time hours older than this unit's files); docs/canonical intact (CC414372/8C987240/66808985/6D3FD03B). gate-validator x3 PASS_WITH_RESERVATIONS (round 1: 6 mutants, 2 SU
> RVIVED [dep range + forward/self checks]; round 2: those 2 KILLED, 21 mutants total; round 3: 10 mutants of the round-2 fixes, ALL KILLED; builder mutation harness independentl
> y confirmed, files restored sha256-identical). spec-auditor x2 (round 1: 3 MAJOR + 8 MINOR + 5 NIT; round 2: all three MAJOR DISCHARGED, 2 new/escalated MAJOR + 7 MINOR arising
> from the fixes - all addressed). 702/702 pytest py -3.12 (was 610 at .selection; +92), 149 product JS/0 fail unchanged (114 terminal + 35 apps/desktop). Work ec7d8eb, evidence
> /register 17974b8. gate/phase-15d UNTAGGED. NEW U35 (per-task scoped context not delivered to workers - the decomposition drives graph/ordering/routing but every worker still g
> ets the OBJECTIVE entry, so artifacts differ only by task id; disclosed in the module docstring, inv 8 not violated) + U36 (control_plane/orchestration/live_flow.py imports ada
> pters.frontier.claude_code + conductor_spawn at module scope - same shape as the .selection MAJOR-1, confined to the convenience factories since LiveGovernedFlow takes an injec
> ted ConductorHandle; both reviewers judged the carry defensible). OWED to .gate and recorded not glossed: the SUBSTANTIVE 15D criteria are still outstanding - live models, one
> bounded LIVE debate, live conductor succession, the s13 OP-8 interactive ConPTY conductor pane, voice-in; this sub-step proves the governed loop MOCK-FIRST only (correct s10.4
> posture, small fraction of the phase gate). Also owed: gate_id non-determinism (secrets.token_hex in the shared gates engine makes packets non-byte-replayable), Backend Protoco
> l does not declare calls:int, 'workers':'mock' is a literal (contained - a live worker leg is now unrepresentable), no budget OBJECT in this flow (caps present are governor all
> owance + _max_waves + backend timeout), ruff unavailable so the ruff-clean rule is UNVERIFIED for this unit. CONSTRAINT for phase-15d.debate: one bounded LIVE debate per direct
> ive s11 15D - debate_service/ already exists (Phase 7, gate/phase-7): <=5 rounds, evidence-cited assertions, dissent preserved VERBATIM, per-debate hard budget + per-caller quo
> ta + global cap, clean budget-exhaustion cutoff, non-conductor caller accepted (s2.8). Drive it through the live-capable binding as .flow did; MOCK-FIRST - the live leg stays S
> KIP-WITH-RECORD unless R8 s6 [OPERATOR] live-terms are discharged AND a real live call is produced (s10.4), never present a mock leg as live. Budgets are HARD caps and now mean
> real tokens/money: smoke-scale prompts only, and any live smoke must spawn -> exercise -> TEAR DOWN within the unit (D-LOOP-1). Reuse the .flow honesty machinery (ATTEMPTED_LE
> G, verified-checkpoint rule) rather than inventing a second leg vocabulary. Then .succession (kill the conductor mid-run, resume on a DIFFERENT backend, zero loss, then restore
> the selection - restore_operator_selection is landed and refuses a non-succession state; note U34), then .gate (HIGH-STAKES, MANDATORY gate-validator, discharge U33/U34/U35/U3
> 6 + the .selection R2/R3 + F1/F4, re-confirm tag lineage + the four frozen canonical hashes + config/live_operation.json gitignored).",
71 | "2026-07-20 iter44: .debate DONE (phase-15d.debate). ONE bounded debate driven through the live-capable binding, MOCK-FIRST, on top of the Phase-7-gated Debate Service (not
> reimplemented): BackendDebater (any Backend, no branch in the service), fail-closed statement parse (unusable reply => refusal with NO citations, never a fabricated ref), per-
> debater leg classification reusing live_flow's vocabulary (imported, not redeclared). RECOVERY PROVENANCE: iter 43 crashed a second time mid-unit (D-LOOP-1); untracked new file
> s survived INCLUDING a fully-written evidence report claiming a passed gate-validator, a passed spec-audit and mutation statistics. That report was NOT trusted - its counts wer
> e probably wrong against its own tree (claimed 789/+87/53+34, measured 797/+95/60+35) - and was REPLACED wholesale. That decision was LOAD-BEARING: two independent reviewers ru
> n fresh on the recovered tree BOTH found a MAJOR defect in the unit's CENTRAL honesty claim, which the discarded report asserted the opposite of ('Refutation attempt FAILED').
> THE DEFECT: a 'live' leg (= a real provider ran) was reachable with NO live call - (a) insistence accepted a ClaudeCliBackend SUBCLASS overriding generate that spawned nothing,
> and the unit's OWN integration test did exactly that, asserted legs=='live', and called it 'The ONLY path to a live leg' (a mock published as a real-provider result, s6/s10.4)
> ; (b) a genuine backend with calls==0 and reported_model hand-set; (c) a STALE reported_model from an earlier debate where every call in THIS one failed (reported_model is neve
> r cleared, calls is a LIFETIME counter). FIX: exact-type classification (type(b) is ClaudeCliBackend, not insistence); NEW ClaudeCliBackend.reported_model_at_call stamped insid
> e generate ONLY when the CLI actually reported a checkpoint, so a checkpoint is datable to a specific successful call; verification_for requires exact class + non-blank STR che
> ckpoint + int(non-bool) stamp STRICTLY GREATER than a bind-time calls snapshot + evidence a call was spent (calls_before=None can never verify - absence of evidence is not evid
> ence); attempt_live_debate snapshots calls at bind time and threads calls_before through EVERY leg/verification site so judgements describe THIS debate not the object's lifetim
> e. Round-2 auditor MAJOR: the demotion reached 'legs' but not 'debater_models' (verification_for never consulted calls), so an artifact published legs:skipped BESIDE debater_mo
> dels:{verified:true} - the weaker claim in one field, the stronger in the field carrying the evidence; fixed by moving the spend check INTO verification_for AND making _assert
> debate_legs_honest enforce the REVERSE direction (a checkpoint on a non-live leg is refused). Round-2 validator: build_debate_report still made TWO verification.get calls (guar
> d + emit) while its comment claimed 'One lookup, one truth' => resolved ONCE into a snapshot passed to both. CONSEQUENCE TAKEN DELIBERATELY: 'live' is now unreachable end-to-en
> d without spawning a real claude process, so NO test produces one (pinned by test_no_leg_in_this MOCK_FIRST_suite_can_reach_live); the positive live contract is tested only at
> the classifier level with docstrings saying so - the same posture .flow used. RESIDUAL, recorded as U43 not claimed away: exact type constrains an object's CLASS not its BEHAVI
> OUR, so forging both stamps on a genuine backend, __class__ reassignment, and instance-level generate replacement all still reach live and CANNOT be closed in-process; every AC
> CIDENTAL/mock-SHAPED route (subclass, duck type, renamed class, metaclass liar, __getattr__ proxy, attribute injection, stale/unstamped checkpoint, bool/int) is verified refuse
> d. Also: position (2000) + diagnostic text (200) bounded with MARKED truncation before entering immutable artifacts (position was unbounded and the constant's comment claimed o
> therwise); role-whitelist rationale WITHDRAWN in module AND both test docstrings (SovereignPolicy already refuses a gate promoting an entry it authored - the stated threat did
> not exist); module header no longer claims 'nothing here spawns a claude process' (false with backend=None) nor misattributes the freshness rule to build_debate_report; the 'ra
> n' comment no longer claims a derivation the success paths don't perform. ModelWorkerAdapter gains a read-only 'backend' property (bind a supervisor-spawned node's backend inst
> ead of bypassing the live-spawn gates). FIVE findings were against MY OWN TESTS - a vacuous I-X3 loop (reused node ids => passed with zero releases), two tautological assertion
> s, a name stronger than its body, and one whose PREMISE was wrong (test_ran_reflects_a_backend_that_was_already_spent asserted another debate's LIFETIME spend should make THIS
> debate ran=True 'because over-reporting is honest'; over-reporting is safe for WHETHER a call was spent, not a licence to bill this debate for another's) - all rewritten, not a
> rgued away. I ALSO claimed an EQUIVALENT mutant (removing 'spent and' from debater_leg) and the round-3 validator REFUTED it with a racing-counter input: the two functions read
> the counter SEPARATELY, the 'and' takes the earlier fail-closed reading; claim withdrawn, comment inverted, case pinned. Second self-coverage gap it found: the bool-exclusion
> guard was unpinned (test used calls_before=5 where True==1 is caught by magnitude, so its docstring described a case it never built) - rewritten to calls_before=0, mutant now K
> ILLED. REGISTERS: U37-U45 written to UNRESOLVED_ISSUE_REGISTER.md - they were cited in code but existed in NO register (a real disclosure gap the auditor caught). Review rounds
> : R1 validator PASS_WITH_RESERVATIONS + auditor FINDINGS (recovered tree); R2 validator FAIL + auditor 3 MAJOR (first fixed tree); R3 validator PASS_WITH_RESERVATIONS (committe
> d tree) - all its blocking reservations discharged. spec-auditor confirmed inv 1/2/4/8/10/11/13/14/15/16/17/18/20/30 clean, no prohibited drift, Decimal in every cost path. NO

> every refusal reporting host_enumeration -> exactly the id-asserting legs red while the forged leg stayed green); defeated NOTHING in the binary allowlist across ~30 wrapper/r
> ename/Win32/UNC/ADS forms; suites confirmed 1303/222/175. The concurrent spec-audit of the same state returned 0 BLOCKING, 2 MAJOR, 13 MINOR, PROHIBITED DRIFT: NONE -- neither
> MAJOR a fail-open, both honesty defects, one CREATED by the fix commit. s3.4 says fix, never soften, so they were fixed and the reviews RE-RUN against the fixed tree.\nROUND 1
> MAJORS FIXED: (1) `vram_admission` conflated three structurally different refusals and the receipt leg named \"a local pane that does not fit VRAM was refused\" fired on the BU
> DGET-PROVENANCE branch -- the busy-host 1MB squeeze FALSIFIED the budget, so nothing was measured and nothing about fit was proven; cross-family id borrowing was closed at .tic
> ket, intra-family was not. Split `vram_budget_unestablished` out, and made the self-check COMPUTE its VRAM budgets from the host's own residency snapshot (new `--emit-residency
> ` contract) so `squeezed = used + footprint - 1` stands above what is resident and falls short of the target, making the FIT gate what fires on any host. (2) a local option rea
> d `available:true` in host states where the gate refuses every local pane -- correct at 16B when residency was a display chip, false once 17B made the planner an authorization
> gate; `local_admission_reason()` now greys them with the reason.\nROUND 2 (fixed tree) VERDICT: FAIL, four MAJORS, all fixed: (A) the greying was NARROWER than the gate -- `__au
> thorize_local` also refuses every local pane when the `ollama` BINARY is absent (`runtime_absent`), reachable because the model list comes from the daemon over HTTP while the l
> aunch needs the CLI, a divergence worker_pane_spawn's own refusal text documented; the validator reproduced it. Both host-wide conditions now covered, each naming itself, and t
> he property pinned in BOTH directions by a test that drives three host states through the picker AND the real authorize_worker_pane and requires agreement. (B) the greying leg
> was a COIN FLIP on daemon state -- falsifying a budget needs something resident, so on an idle host it silently did not run while ok:true was still emitted, and its fallback no
> te cited the WRONG test file; it now forces the RUNTIME-ABSENT condition by scrubbing only the resolved ollama binary's directory from PATH for its own children (the daemon sta
> ys reachable so the models are still enumerated), is unconditional, and a failed scrub is loud. The first attempt scrubbed the WHOLE PATH, which also took `py` and produced zer
> o options -- caught by the leg itself. (C) the newly-split `vram_budget_unestablished` was itself reused for the budget-vs-planner disclosure mismatch, a branch where the budge
> t WAS established -> own id `vram_budget_mismatch`, and the undecidable-fit branch split out as `vram_footprint_unknown`. (D) `host_residency@1.0` was pinned in code with no sc
> hemas/ file, no register row, and a predicate validating only the schema string while the self-check did load-bearing arithmetic on the unvalidated fields -> the predicate now
> validates every field a consumer computes with; the missing FILE is U104, deferred to 17d with U90/U99/U101.\nROUND 3 (fixed tree again) VERDICT: FAIL. It confirmed all four ro
> und-2 MAJORS genuinely fixed and mutation-verified IN BOTH DIRECTIONS (18 mutations, every one RED), then found THREE defects the fixes introduced, all fixed here: the receipt'
> s flagship field still named the OLD condition (`local_greyed_when_budget_unestablished` reading true in a run where the budget WAS established -- the MAJOR-B class recurring i
> nside the MAJOR-B fix; renamed `local_greyed_when_no_pane_can_be_authorized`, named for the PROPERTY); the new conductor shell-metacharacter guard had NO test, so deleting eith
> er line left 230/230 green -- exactly the class the same commit's new worker tests were written to close (added, mutation-proven RED on each line individually); and two unused
> imports orphaned by the de-duplication and the broadened `except`, violating the ruff-clean bar (pyflakes is now clean on every file this unit touched; ruff itself is still una
> vailable on this host and the substitution is recorded). Its MINORS are fixed too: local_admission_reason's completeness claim now NAMES what it excludes and why (per-model fit
> , role_deferred, the structurally-unreachable mismatch), pane_picker's docstrings describe both conditions, the U102 cross-reference is corrected, \"one child\" -> \"its own ch
> ildren\".\nALSO FIXED ACROSS THE THREE ROUNDS: `exe = resolved or `\"claude\"` was a fail-OPEN under the module's own claim that the shell spawns exactly what was gated (-> `__re
> solved_binary`, gate `binary_unresolved`); a frontier authorization reported node_state `\"ready\"` for a node that had not been born (-> launch_authorized, inv 3/27, stale fixtu
> re corrected); `governor_released` was documented \"measured, never asserted\" while the refusal branch compared a sentinel that can never be a holder (-> read from the MINTED
> identity; a real post-acquire leak now reports false); an ambiguous option match silently bound the first candidate (-> refused); `__RESIDENCY_NODE_STATE` de-duplicated; `except
> ResidencyError` widened to `except Exception` plus an isinstance(tags, dict) guard after a daemon answering /api/tags with a JSON ARRAY was shown to take the WHOLE picker down
> via AttributeError -- the BLOCKING-1b shape one exception class over; the shell-metacharacter rule moved into the CONDUCTOR source (one definition, re-exported) and APPLIED to
> the conductor ticket, which had no such check at all, with `>`/`<` added; `refused_by: \"\"` no longer passes as a named gate; the host_enumeration refusal prose no longer tel
> ls the operator they could not have been shown an option they were shown greyed; comments implying estimate:false is reachable corrected (it is not -- an env-supplied budget is
> a stated figure, not a GPU query); the self-check's determinism and \"one megabyte short\" claims scoped to what they deliver; runEnumerator gained per-child `env` so the chec
> k no longer mutates the shell's own environment.\nSUITES FRESH FOREGROUND: pytest 1326 (was 1303), apps/desktop 231 (was 222), terminal 175. The round-3 validator independently
> reproduced 1326/230/175 at its boundary (231 includes the conductor metacharacter test added after it ran). RECEIPT regenerated from the shipped code after every mutation was
> restored byte-identically: ok:true, four DISTINCT gate ids across the fail-closed legs (host_enumeration forged, vram_admission fit with the real arithmetic `\"free VRAM 4982MB
> of 9510MB, 4528MB in use\", worker_role conductor, host_enumeration greyed selection), in_use_after_release 0. Its green is EARNED: reverting the greying rule -> ok:false `\"the
> picker still offered local options as available (43 local ...)\"; mis-stamping the fit gate -> ok:false on exactly that leg; both reproduced independently by the round-3 valid
> ator, which added a third (breaking the PATH-scrub target -> the guard fires).\nREGISTERED not fixed: U104 (a third governed cross-process envelope pinned in code with no schem

```

> as/ file -- deferred to 17d because schemas/ is in the Phase-0 frozen set and one unit should write all three; what was NOT deferred is the predicate, since U99's \"the predica
> te is stronger than a schema\" mitigation did not transfer). HONEST LIMITS: the self-check's pinned budget is deliberately generous and therefore fictional as a capacity claim
> -- it tests admission MECHANICS and the ticket discloses estimate:true; the budget-unestablished greying is proven only in pytest, since the in-Electron leg forces the runtime
> condition instead; ruff unavailable, pyflakes substituted and recorded.\\nWHY next_step is `phase-17b.ticket-revalidate3` and NOT `.spawn`: round 3's three findings were fixed A
> FTER that pass ran. They are mechanically verified (conductor guard mutation-proven red on both lines, pyflakes clean, the renamed field present and the old name absent in a re
> generated ok:true receipt, full suites green) but NOT independently reviewed, and three rounds have each found something in the previous round's fix -- closing on the builder's
> own word is the softening s3.4 forbids. NEXT UNIT'S FIRST ACT: a fresh foreground gate-validator on this committed state; only on PASS does .spawn begin.\\nSCOPE HONESTY unchan
> ged: nothing here spawns a session, U70's spawn half and U58's live legs are OPEN, the picker click is still not wired to a ticket, operator finding F3 is not discharged, no li
> ve model call, no credential (env NAMES only), no new provider. D-LOOP-1 verified: no session, lease, gateway or Electron process outlived the unit; a lease leaked into the ope
> rator's REAL ledger by an early draft of test_one_matching_option_still_binds (which used the default ledger) was found by the round-3 validator, the test now uses a temp ledge
> r, the ledger was cleared and re-running the relevant suites leaves it empty.\"
114 |   \"2026-07-26 iter78: phase-17b.ticket-revalidate3 ran the OWED independent pass; the gate-validator PASSED (PASS_WITH_RESERVATIONS) and a concurrent spec-audit of the same s
> tate returned PROHIBITED DRIFT: NONE with one MAJOR; everything both reviews found is FIXED and committed (work d51cabb, evidence d3bcb1c) and .ticket now CLOSES -- next_step i
> s phase-17b.spawn. State reconciled to tags FIRST: gate/phase-17a present, no gate/phase-17b, next_step agreed with HEAD 09f0fda -- no reconciliation commit; the working tree c
> arried only the pre-existing untracked apps/desktop/package-lock.json. THE UNIT'S FIRST ACT, as directive s3.4 requires, was a fresh FOREGROUND gate-validator on the COMMITTED
> state (D-LOOP-2: nothing from a prior turn survives). VALIDATOR VERDICT: PASS_WITH_RESERVATIONS (3 MINOR). It re-derived everything itself -- suites at 1326/231/175, the receipt
> t regenerated in-Electron with ONLY run-identity fields differing from the committed one (every gate, budget figure, argv, gate id and the flagship boolean byte-identical) -- a
> nd mutation-proved all three owed round-3 fixes: each conductor metacharacter guard line deleted ALONE took the JS suite to 230 pass / 1 fail on the same test; the greying leg
> was attacked three ways (bogus scrub target gives exit 1 'not attempted'; whole PATH scrubbed gives exit 1; and the decisive one, local_admission_reason forced to None, gives e
> xit 1 'still offered local options as available (43 local, reason-null, ticket refused_by-runtime_absent)', proving the leg tests picker-vs-gate AGREEMENT and not merely the sc
> rub); ruff confirmed genuinely absent and pyflakes clean over all 16 Python files the unit touched. It also drove 41 forged tickets through the real shape contract with two pos
> itive controls, and confirmed 0 drift over all 23 frozen entries, no remotes, names-only credentials, an empty real lease ledger and no surviving process. THE SPEC-AUDIT MAJOR,
> FIXED: a LOCAL authorization reported chrome.node_state 'ready' for a node with no process (inv 3/27) -- the same ticket says containment.supervisor_bound false. The branch DE
> RIVED the state from the ResidencyPlanner decision and RESIDENT maps to 'ready'; enumerate_pane_picker seeds every /api/ps model RESIDENT, so re-selecting a model the daemon al
> ready serves is the NORMAL case (this unit's own receipt shows running_vram_mb 4528). It survived three rounds because three artifacts asserted the local branch was 'already ho
> nest' -- the constant's comment, a test docstring, and block 2 SE -- and deriving is not the same as being true: what it derived from is a fact about a MODEL. The scheduled-loa
> d case reads 'loading', harmless enough to hide the resident case, and the receipt recorded local_residency but never chrome, so its green could not see the field at all. FIXED
> : both localities report launch_authorized, chrome.residency keeps the residency fact where it is true, _RESIDENCY_NODE_STATE is no longer imported by worker_pane_spawn; pinned
> by two tests incl. the reachable resident case; and the receipt now RECORDS AND ASSERTS local_node_state plus frontier_node_state -- reintroducing the defect on either branch
> turns the in-Electron receipt RED (exit 1) on exactly that leg, both mutation-proven. ALSO FIXED: the basename normalisation run in REVERSE (validator MINOR-2) -- executableBas
> ename strips an NTFS alternate-data-stream suffix and trailing padding so a disguised claude is caught, and that same stripping made ollama.exe:claude.exe normalise to 'ollama'
> and be ACCEPTED as a lease-free, I-X3-UNCOUNTED local ticket while Win32 executes the STREAM (FRONTIER_TOKENS never saw it: it only scans argv and ':') is not one of its bounda
> ries); streams and padding are now refused OUTRIGHT on launch.executable, the field that decides what runs, with stripping kept for COMPARISON, each half mutation-proven indepe
> ndently RED -- and stated as the VALID shape and negated, because written as a positive stream match the optional drive group backtracks out of the way and C:/bin/ollama.exe re
> fuses itself, which is exactly what the first attempt did and what its own test caught. Spec-audit MINOR-1: the or-ollama fallback in adapters/local/ollama_session -- the resol
> ved-or-claude shape the binary_unresolved gate exists to refuse, since a blank executable becomes a bare name the shell PATH-searches AFTER the gate ran and 'ollama' is precise
> ly the basename the allowlist accepts -- now raises. NIT: containment.requires asked the shell to perform residency_release_on_session_exit, a release that by this build's own
> design cannot happen (the reservation dies with the emitter, as U96 item 3 says); the local branch now lists nothing to release and states the lifetime instead. MINOR-4: the re
> ceipt scope_note's 'if the resident set changes mid-run every leg throws' was false of the authorized leg (its generous budget can stay green if the set SHRINKS) -- replaced wi
> th what is actually established. REGISTERED not fixed: U105 (the credential scrub list is measured in the PYTHON EMITTER's environment and applied to the ELECTRON SHELL's -- so
> und only while they match, and 17B itself made divergence reachable via per-child opts.env; fail-open direction, no product path exercises it, owner .spawn where the union shou
> ld be taken; s2.2 is NOT violated, only NAMES cross), U106 (ADAPTER_EXECUTABLE duplicates a Python-owned fact; deliberately NOT fixed by letting the ticket declare its own bina
> ry, since disbelieving the ticket about itself is the point; travels with U104's schema unit), U107 (the headless dispatcher still calls request_load unguarded and can act on a
> displacement the worker path refuses -- latent, no product caller -- plus an append-only CORRECTION to U96 whose 'this build refuses to displace ANYTHING' is true only of work
> er_pane_spawn, and a record that the two paths now deliberately differ on node_state), U108 (CLAUDE.md documents the pytest command as plain 'python', which fails on this host
> with 71 collection errors because the default python is 3.14.6 -- only py -3.12 runs the suite -- and terminal/ has no package.json so npm test there is ENOENT; the round-4 val
> idator hit exactly this. NOT fixed by editing CLAUDE.md: this loop does not rewrite the operator's instruction file to match the machine; flagged for the final report). APPEND-
> ONLY CORRECTION to iter77's note and evidence block 2 SF: 'four distinct gate ids across the fail-closed legs' is four LEGS across THREE distinct ids -- the forged leg and the
> greyed-selection leg both report host_enumeration, so a defect making every refusal report host_enumeration would leave two of the four green. Same over-claim class the unit sp
> ent three rounds removing from the code, surviving in the prose. SUITES FRESH FOREGROUND on the final tree: pytest 1328 (212.81s; was 1326 -- two honesty tests replacing one, p
> lus the argv-builder test), apps/desktop 232 (was 231), terminal 175. pyflakes clean on every file touched; ruff still unavailable on this host and the substitution is recorded
> (the validator independently confirmed the absence genuine). RECEIPT regenerated from the shipped code after every mutation was restored: ok:true, local_node_state and frontie
> r_node_state both launch_authorized, in_use_after_release 0. WHY .ticket CLOSES HERE and next_step is phase-17b.spawn: the owed pass ran and PASSED. The fixes above were made a
> fter it and are verified by this unit's own mutations -- the same position iter77 refused to close on. The difference is that .ticket is a WIP CHECKPOINT inside 17B, not a gate
> : gate/phase-17b closes at .close with a mandatory gate-validator over the whole track, and these fixes are inside its scope. Spending further whole units re-reviewing a checkp
> oint that has now passed its owed pass, while U70's spawn half and U58's live legs stay untouched, would be its own dishonesty about where the risk is. .spawn's first act carri
> es these five fixes into its review. SCOPE HONESTY unchanged: nothing here spawns a session, U70's spawn half and U58's live legs are OPEN, the picker click is still not wired
> to a ticket, operator finding F3 is not discharged, no live model call, no credential (env NAMES only), no new provider. docs/canonical/, mcp_server/ and schemas/ untouched. D-
> LOOP-1 verified: the real lease ledger is empty and untouched (timestamp 10:40, before this unit's runs), no scratch ledger remains, no Electron or gateway process survives.\"
115 |   \"2026-07-26 iter79: phase-17b.spawn LANDED as a WORK-IN-PROGRESS CHECKPOINT (work 0b58e84, evidence 534b2e9): a picker selection now LAUNCHES a governed live worker session
> , closing U70's spawn half and the machine-checkable part of operator finding F3. State reconciled to tags FIRST: gate/phase-17a present, no gate/phase-17b, next_step agreed wi
> th HEAD 6b9295a - no reconciliation commit; the working tree carried only the pre-existing untracked apps/desktop/package-lock.json. WHAT SHIPPED: apps/desktop/picker/worker-sp
> awn.js, the ONLY place the shell executes a launch ticket - injectable so every governance rule is covered headlessly (admission BEFORE the ask so nothing is counted for a sess
> ion that cannot be born; pane occupancy; the session key chosen before the ask; authorization-only spawn under the PYTHON-minted node id; the SS2.2 scrub applied to the same en
> v the names were classified over, with a leftover ABORT; terminal handback on every failure path; exit/kill/quit release) - plus the main.js wiring (spawnFromSelection LAUNCHES
> instead of recording; post-spawn ROLLBACK so 'a throw means nothing was born' is true; conductor-pane guard; chrome revised when a session ends and pushed over a new read-only
> pane:chrome stream), the renderer reporting the real launch state, and the U105 fix. U105 WAS A REAL FAIL-OPEN ON THIS HOST, not tidiness: Python's os.environ UPPER-CASES keys
> on Windows while Node keeps the created case and deletes by exact spelling, so a mixed-case credential var was named in the ticket under a spelling the shell could not delete

```

```

> by AND REACHED THE CHILD - reverting the fix reproduces exactly that (shell_only_name_absent_from_child:false, receipt exit 1). The first version of that leg used an UPPER-CASE
> name and stayed GREEN with the fix reverted; it was rewritten against the divergence that is real here. SUITES FRESH FOREGROUND: pytest 1338, apps/desktop 257, terminal 175 (b
> aseline 1326/231/175); pyflakes clean on every Python file touched. D-P16-0 receipt PHASE17B_SPAWN_SELFCHECK.json ok:true (Electron 31.7.7): a real 'ollama run qwen3:8b' and a
> real 'claude --model claude-fable-5' RUNNING in real panes, each matched to its own binary at the node-pty boundary before its cwd/env is read as evidence, each workspace-bound
> and credential-scrubbed (7 names, PATH preserved), each rendering into the renderer buffer; the frontier lease durable, session-keyed, cross-process visible, released on exit
> (in_use 0, surviving_pids [], the REAL ledger untouched); a fabricated option refused by host enumeration with no session and a launch_refused pane; an occupied pane refused wi
> thout disturbing the running session's process, RECORD, held terminal or chrome. REVIEWS RAN FOREGROUND IN THIS UNIT (D-LOOP-2, not deferred): gate-validator FAIL - BLOCKING-1
> was real and mine: refuse() merged into the pane's record, so refusing a click on a pane ALREADY RUNNING a worker overwrote its 'running' record with 'refused', and every relea
> se gate keys on that state - the operator's durable I-X3 terminal then became unreleasable for the LIFE OF THE SHELL (not on exit, not on kill, not on quit; dead-holder reaping
> cannot fire because the holder is the shell). Two clicks and the operator is locked out of their own subscription. FIXED (a refusal never overwrites a record this launcher sti
> ll holds; the attempt's OWN in-flight record is exempted by session key) and mutation-proven RED both ways, headless AND in-Electron. Its MAJOR-1 (the same refusal repainted a
> LIVE pane as launch_refused/ governed:false and persisted it) and MAJOR-2 (neither the suite nor the receipt could SEE either defect - the old occupied test refused into a pane
> never launched into, and the receipt leg asserted only the OS process) are fixed too. spec-auditor: PROHIBITED DRIFT NONE with 3 MAJOR, all fixed - chrome kept saying running/
> governed after the session died and baked that into the recovery snapshot; the receipt's scope_note claimed for the FRONTIER leg facts only the LOCAL leg established (the leg t
> hat actually consumes a subscription terminal); and 'a spawn that throws means nothing was born' was an assumption the wiring did not honour (five steps ran AFTER manager.spawn
> , so a throw there would release the terminal while a live claude kept running - an UNCOUNTED live frontier terminal). MINORS fixed: the untested quit-path sync release, the ne
> ver-assigned pid, ptySpawnObserved attribution, a worker launchable into the CONDUCTOR pane (guarded only by CSS), 'never throws' not enforced, an exact-spelling leftover guard
> blind to the very case divergence U105 exists for, two stale comment blocks, a badge stuck on 'selected', the scratch-ledger disclosure, gate-id borrowing on the new env payload
> ad, and a dead env restore. REGISTERED not fixed: U109 (the shell does not verify a ticket's node_id relates to its pane - that rule is Python's and duplicating it is the U106
> class), U110 (an ended worker pane has no per-pane relaunch control; the picker is the same governed path - 17E), U111 (the receipt's live legs consume a real subscription term
> inal against a SCRATCH ledger, so the real governor does not see them for that window - inherited from 17A .pty, now disclosed in the receipt). WHY next_step is 'phase-17b.spaw
> n-revalidate' and NOT '.legs': the reviews ran against the PRE-FIX tree; everything above is so far verified only by MY OWN runs. Directive s3.4 - a FAIL is fixed in this or th
> e next iteration, never softened, and the fixed state has to be independently confirmed before the track moves on. NEXT UNIT'S FIRST ACT: a fresh foreground gate-validator + sp
> ec-auditor on the COMMITTED state; only when they pass does .legs (U58 live worker CANDIDATE -> gates -> conductor synthesis) begin. SCOPE HONESTY: no prompt was sent to any mo
> del, no model answer is claimed, U58 is UNCHANGED and OPEN, and the containment the ticket lists as owed (permission-profile binding U78(a), OS job object U25) is unchanged. D-
> LOOP-1: the real lease ledger is empty, no scratch ledger remains, surviving_pids [], no orphan process; no credential read, stored or transmitted (env NAMES only); no new prov
> ider.",
116 | "2026-07-26 iter80: phase-17b.spawn-revalidate ran the OWED independent pass; the gate-validator returned PASS_WITH_RESERVATIONS and the spec-auditor PROHIBITED DRIFT: NONE
> , and BOTH found the SAME new MAJOR independently - everything both found is FIXED and committed (work aa9fb14, evidence c8a45ce), so .spawn CLOSES and next_step is phase-17b.1
> egs. State reconciled to tags FIRST: gate/phase-17a present, no gate/phase-17b, next_step agreed with HEAD 0ec6489 - no reconciliation commit; the working tree carried only the
> pre-existing untracked apps/desktop/package-lock.json. THE UNIT'S FIRST ACT, as directive s3.4 requires, was a fresh FOREGROUND gate-validator + spec-auditor on the COMMITTED
> state (D-LOOP-2: nothing from a prior turn survives). THE CONVERGENT MAJOR, and .spawn introduced it: markWorkerPaneChromeEnded corrects a worker pane's chrome on an exit/kill
> EVENT, so a death WITHOUT teardown - SIGKILL, a main-process crash, power loss, i.e. precisely what a recovery module exists for - leaves {node_state:"running"}, governed:true
> } on disk; the fold carried it verbatim and the renderer maps node_state=="running" to the badge text 'live'. On the next boot paneSeq restarts at 0, so the operator's first
> NEW worker pane takes the very id most likely to be stale, and a brand-new, empty, unadmitted pane came up badged 'live' for a process that died with the last shell - with nee
> dsRelaunch:false so no interrupted-notice contradicted it. It was disclosed only in a code comment, sitting under TWO other comments asserting the opposite ("Restoring it clai
> ms no live node", "node_state stays awaiting-governed-spawn"). Before 17B a worker chrome could only say selected_awaiting_governed_spawn/governed:false, so this class of li
> e was unreachable until .spawn made it reachable. FIXED: a reconstructed pane has NO live session by construction (every worker comes back reattach:false/admitted:false), so _s
> anitizeRestoredChrome rewrites a stale live node_state to 'session_interrupted' and forces governed:false AT THE FOLD - not at capture, where 'running' was TRUE when written -
> keeping the fact in a DERIVED 'interrupted_from' (the pane WAS running) in place of the false claim (it IS running); the model badge is untouched and both false comments are co
> rrected. THE SECOND MAJOR: two of the three .spawn MAJOR fixes were invisible to EVERY check in the repo - reverting the ended-chrome revision or the post-spawn rollback left e
> verything green, because both lived in main.js (not requirable headlessly; it calls app.whenReady() at load) and the receipt had no field for either, since the self-check kills
> its panes in 'finally' AFTER the last assertion; the conductor-pane guard was in the same state, and the .spawn report listed all of them as FIXED in a table whose other rows
> carry explicit mutation proof - certainty by adjacency. FIXED by extracting all three to picker/pane-wiring.js, pure + injectable (15 unit tests) plus TWO new receipt legs that
> read what the OPERATOR's badge is drawn from; every post-spawn step is now inside the rollback with a test each, including the pid read that sat OUTSIDE it (a throw there is r
> ead by the launcher as "nothing was born" while a live session is registered and running - spec-audit MINOR-4). MUTATION-PROVEN: eight headless mutations, every one RED, each
> applied alone with the file restored byte-identically; and TWO full in-Electron mutation runs - disabling the chrome revision gives exit 1 / ended_chrome_revised:false / node_
> state still "running", and disabling the conductor guard gives exit 1 AND actually LAUNCHES a live worker into pane 1 (started_no_session:false), which is what makes that gua
> rd load-bearing rather than cosmetic. ONE MUTATION CAUGHT A BAD TEST OF MINE: the first session-scoped-catch test stayed GREEN because it drove a SECOND launcher, whose records
> are its own, so the catch's get(paneId) returned an empty record either way and the mutation was invisible - the exact "a fix whose test cannot see it" defect the reviews ha
> d just raised, reproduced inside the fix for it; rewritten to toggle a faulting dependency on the SAME launcher that already holds a live session, driving both pre-record depen
> dencies. ALSO FIXED: the outer catch was not session-scoped for pre-record faults (a throw from isSupervised/hasLiveSession released the LIVE session's durable terminal and ove
> rwrote its running record - BLOCKING-1's harm by a second route, latent but real); the case-insensitive credential leftover guard had NO case-divergent test so it passed identit
> cally against the exact-spelling implementation the fix replaced (both reviewers, independently); the LOCAL leg's scrub check was case-SENSITIVE while the frontier leg added by
> the previous fix was not; the ticket shape contract accepted ANY launch.cwd, so "the ConPTY is bound to the governed workspace" rested on the producer plus one in-runtime as
> sertion; a forged renderer-supplied 'verified:true' reached a refused pane's badge (Python had closed the same hole on the issue path); a refusal returned the OTHER session's i
> dentity as this attempt's result (launched:false beside state:"running"); occupied_chrome_intact compared ONE field while the defect flipped three; the scope_note's "can nev
> er\" about the operator's real ledger was stronger than the code established, so teardown now QUIESCES pending releases before restoring the env; and the 1 TiB probe budget is
> disclosed in the receipt rather than only in code. THE APPEND-ONLY NOTE'S LITTER DIAGNOSIS IS RETRACTED: the validator probed the asserted mechanism directly and a release rew
> ites nothing (byte-identical against an existing ledger, creates nothing against a missing one), and the litter did not reproduce in five subsequent runs - so instead of acting
> on an unverified cause the check now MEASURES the two facts that matter and gates ok on them (scratch_ledger_removed, real_ledger_unchanged as a byte comparison against a pre-
> redirection read), and a straggler will be learned from a failing run. SUITES FRESH FOREGROUND: pytest 1338 (213.00s), apps/desktop 277 (was 257), terminal 179 (was 175); pyfla
> kes clean on both Python files in scope; ruff still unavailable (recorded substitution). RECEIPT regenerated after the mutations, ok:true (Electron 31.7.7): conductor_pane_refu
> sed against the REAL pinned pane-1, ended_chrome_revised (session_killed/governed:false/badge kept), surviving_pids [], frontier_in_use_after_exit 0, real_ledger byte-identical
> . D-LOOP-1 verified after ALL THREE full in-Electron runs: no surviving electron.exe, .sovereign_store/leases/ holds only terminal_leases.json, and the throwaway mutation harne
> ss was deleted. REGISTERED not fixed: U112 (OpenCode is absent from the governed picker->launch path while the track text says "Ollama/OpenCode" and invariant 23 makes it fir
> st-class - pre-existing since 16B, fails closed, but the report's "does not claim" list omitted it), U113 (node-pty AttachConsole stack noise in the one artefact an operator
> reads to judge a live run - it would camouflage a real crash), U114 (pane:new still accepts a renderer-supplied file/args, so a supervised-but-UNTICKETED model process is reach

```

```

> able from the least-trusted surface - it bounds the \"only place a launch TICKET is executed\" claim, which is true, against the stronger reading \"the only place the shell sta
> rts a model process\", which is not), U115 (the live OpenCode worktree test failed once under the validator's own concurrent Electron run - not robust to concurrent local-model
> load); plus append-only STATE corrections for U70 (spawn half RESOLVED, mode-toggle half still OPEN), U100 (RESOLVED, headless-only proof restated) and U105 (RESOLVED, and it
> was a real fail-open on this host), and a correction to U109's RATIONALE (the file already duplicates two Python-owned facts deliberately, so \"the shell never duplicates a Pyt
> hon rule\" was false; the honest posture is that it duplicates when disbelieving the ticket about ITSELF is the point). SCOPE HONESTY: no prompt was sent to any model, no model
> answer is claimed, U58 is UNCHANGED and OPEN, and the containment the ticket lists as owed (permission-profile binding U78(a), OS job object U25) is unchanged. NO TAG: gate/ph
> ase-17b closes at .close with the whole-track evidence, exactly as 17A closed. NEXT UNIT: phase-17b.legs - a LIVE worker publishing a CANDIDATE over MCP -> real gates -> conduc
117 | tor synthesis (U58), minimal live exchanges, D-LOOP-1 teardown in-unit.\"
> \"2026-07-26 iter81: phase-17b.legs LANDED as a WORK-IN-PROGRESS CHECKPOINT (work 12fc2e9, evidence b3f513f) and U58's WORKER half is DISCHARGED ON A LIVE RECEIPT. State rec
> onciled to tags FIRST: gate/phase-17a present, no gate/phase-17b, next_step agreed with HEAD 17ac413 - no reconciliation commit needed. THE TREE WAS NOT CLEAN: a prior turn die
> d mid-unit leaving ~630 lines of uncommitted .legs work plus two untracked test files and an evidence JSON showing a FAILED live attempt (legs.workers=attempted, verified=false
> , failed_count=1). That work was reviewed, kept, completed and committed rather than discarded - it was sound; what it lacked was a working live call. WHAT SHIPPED: LiveGoverne
> rFlow accepts injected WorkerHandles so the SAME governed loop runs the deterministic pool or a real supervisor-spawned vendor terminal with NO branch in the governed path (inv
> 4); a live handle is minted only by live_claude_worker_handle, born from spawn_claude_code_terminal so every live gate applies first; and a worker leg is DERIVED from that nod
> e's own evidence row by derive_worker_legs, with _assert_legs_honest refusing a declared leg that contradicts the evidence in BOTH directions - a live claim with no verificatio
> n record is unrepresentable, and an under-claim that would hide real spend is refused too. THREE REAL DEFECTS, each found by a live run FAILING, each fixed test-first: (1) Mode
> lWorkerAdapter never returned `structured`, so the STAGE gate had nothing to evaluate and the live adapter could not complete the flow at all; (2) U60's ROOT CAUSE - recorded f
> or two phases as 'transient loopback flakiness', which is WITHDRAWN: mcp_server/server.py gives each connection handler timeout=60 (an F6 guard) and a live model call runs long
> er, so the SERVER reaps the caller's connection mid-call; the next write then SUCCEEDS into the local buffer (the FIN is unread) and the failure lands on the READ as WinError 1
> 0053, where retrying is forbidden because a delivered request may already have been applied - so the send-side retry never fired. Fixed by checking liveness BEFORE the write (n
> othing has been sent, so re-establishing cannot re-apply anything); a buffered or unrequested byte is a desync and fails closed. The new test drives the server's REAL idle-reap
> path and reproduces the exact WinError 10053 when the fix is disabled; (3) `claude -p` reads piped stdin when stdin is not a TTY, so a supervised worker inherited the supervis
> or's never-EOF stdin and blocked until its timeout - MEASURED on this host: 150 s timeout inherited vs 3.5 s with DEVNULL. Fixed in BOTH live CLI backends (claude_code + codex
> parity). THE LIVE RESULT (docs/evidence/live/PHASE17B_LEGS_DISPATCH_FEED.json, REPRODUCED THREE TIMES at 254 s / 318 s / 277 s): legs.workers=live, worker:worker-claude-live=li
> ve, evidence verified=true with the CLI-reported checkpoint claude-opus-5 dated to a call spent in that run, stage gate PASS 1/1, acceptance PASS, accepted_count 1, live_worker
> s_owed.owed=FALSE derived from the packet's own evidence, torn_down=true. A LIVE claude_code worker was resolved BY DESCRIPTOR, published a CANDIDATE over MCP, the real gate en
> gine read the stored bytes back and accepted them, and the conductor synthesized them into the acceptance packet. The 150 s ceiling the first two attempts used was the real blo
> cker; it is now 420 s, a fail-closed bound on ONE exchange and not a target. BOTH REVIEWS RAN FOREGROUND IN THIS UNIT (D-LOOP-2, not deferred): gate-validator PASS_WITH_RESERVA
> TIONS - it re-ran the suite itself, traced the reconnect for double-apply safety and found it airtight, empirically confirmed the default path launches ZERO subprocesses, and c
> orroborated the live run from filesystem evidence OUTSIDE the artifact; spec-auditor PROHIBITED DRIFT: NONE with 3 MAJOR + 6 MINOR. BOTH found the SAME top defect independently
> and it was mine: a run that spent a real subscription call was stamped with the mock path's replayable DISPATCH_TS, so a 2026-07-26 live dispatch published a packet dated 2026
> -07-24 (inv 11 - provenance must date what actually happened). EVERY finding from both reviews is FIXED in this unit: the real clock on live runs plus a `live_run` block (run_t
> s, measured_elapsed_s, cli_present, the bounds in force) so the receipt dates itself; spec-audit MAJOR-1 - a live worker's real spend VANISHED on any post-call fault because un
> dispatched_feed hard-coded workers:skipped/owed:true, and an auth pause or a second transport failure arrives AFTER generate() counted a call (faults are exactly where under-re
> porting hides, section 6) - the fail-closed feed now carries the flow's worker evidence and derives its legs from it; spec-audit MAJOR-2 - gate (4) CLI-presence keyed on `backe
> nd is None`, so the product's own live path (which MUST inject a backend to widen the timeout) computed cli_present and had it silently IGNORED: a documented gate probably not
> on the chain, with an I-X3 terminal taken before the missing CLI surfaced - the gate now applies to any REAL CLI backend, injected or not, pinned by a test asserting no termina
> l is acquired; validator R4 - the durable lease could strand on exactly the window the factory's own docstring promised was closed; R5 - a published-but-unstructured artifact w
> as orphaned as an unreviewable CANDIDATE in shared memory with no gate record pointing at it, now REJECTED in MCP first; MINOR-1 - a live-bound node that spent nothing was labe
> lled `mock`, which asserts a mock produced work that nothing produced, now `skipped`, and the aggregate is folded from the per-node legs so the two derivations cannot drift apa
> rt again; MINOR-2 - the 'unfakeable' overclaim now carries a STATED LIMIT, the guarantee being caller-scoped per U43 since this suite itself mints fake verifiers to drive the f
> low; R6 - codex stdin parity now tested at both call sites; R9 - the default path is pinned by a test asserting NO subprocess is launched at all, because an app launch may neve
> r spend the operator's subscription; R7/R8/MINOR-3 - docstrings corrected, including what the U60 fix does NOT do (a reap landing between the check and the write still fails cl
> osed, unrecovered) and the structural consequence that a 420 s call against a 60 s handler timeout means EVERY live dispatch is reaped at least once and relies on the reconnect
> : a workaround for a timeout mismatch, not a resolution of it; MINOR-4 - the token-ceiling claim was false and is corrected in place; MINOR-5 - the shell selfcheck assertion is
> KEPT STRICT rather than loosened, because it guards the launch path which must stay mock-first, with its intent made explicit. REGISTER (append-only): U58 worker half RESOLVED
> (the conductor leg is still mock and says so), U60 root-caused + RESOLVED with its prior 'environmental, NOT a governance defect' diagnosis WITHDRAWN, and U116 (no enforceable
> token bound on a live exchange - only the wall clock; smoke-scale is guaranteed by CONSTRUCTION, one subtask to one node), U117 (no cost-to-accepted-output at the first WORKER

tree was clean. THE THREE ACTS THE ITERATION-102 CHECKPOINT NAMED, IN ORDER, ALL IN THIS TURN, ALL FOREGROUND (D-LOOP-2): (1) RE-RAN SHELL_SELFCHECK=fully-live in Electron on (t
his host against THIS tree - 19:57:43Z to 20:00:47Z, ok:true, 36/36, failed_checks empty, source.commit fa3e1a1, tracked_product_tree_clean; the session allowance had reset at
19:00Z 14:00 America/Chicago) so the run started from a fresh budget, which is exactly why it was this unit's first act. Three live exchanges: spoken prompt answered 73 through
> h real WSL Parakeet (mock:false, 62.2 s) into pane 1 s live claude --model claude-fable-5, typed prompt answered 87 in the SAME session, and the dispatch worker. Picker: 49 opt
ions from the host's own daemon, live local qwen3:8b spawned governed holding no subscription terminal. Gate: plan PASS, stage 1/1, acceptance PASS, operator_disposition pendin
> g. Drawer: one row, provenance ev-1 / voice:capture / conductor_voice_feed@1.0, protected verb queued NOT delivered, re-decision refused. I-X3: two live frontier terminals at o
nce, max_in_use_observed 2 of allowance 2. Teardown per D-LOOP-1: both killed, in_use_after_release 0, durable ledger digest 317a684a..d68e92 unchanged, host process list confi
rmed no orphan electron and neither pid alive. (2) BOTH MANDATORY REVIEWERS RAN FOREGROUND ON THE NEW RECEIPT; neither prior verdict carried over. gate-validator PASS_WITH_RESE
RVATIONS - proved exact-sourcing BY CONTENT not by the timestamp (scope_note, two owed keys, dispatch.objective and the cause-first engine reason exist only in this tree), veri
fied 35 of 35 check assignments present so no check was skipped by an early throw, wrote its own ~40-mutant adversarial harness against every verdict rule, re-reproduced the it
eration-100 drawer defect in BOTH orderings (refused now), re-ran every suite and both mutation harnesses itself, and executed the real no_placeholders criterion to answer the
gate-softening question independently: NOT SOFTENED. 5 must-fix, ALL DOCUMENTATION-LEVEL. spec-auditor FINDINGS - 1 MAJOR, 5 MINOR, 4 NIT, NO INVARIANT VIOLATED, PROHIBITED DRI
FT NONE, tag blocked on two items only. THE DECISIVE DIFFERENCE FROM THE TWO ROUNDS THAT FAILED: every blocking remedy was in docs/, OUTSIDE source.product_paths - both reviewe
rs said so independently - so the receipt was NOT voided and the gate could close in-unit. git diff --stat HEAD over all seven product paths was empty at commit time, verified.
> (3) BLOCKERS DISCHARGED: F1/MF-C, the published gate-refusal exhibit still asserted the real gate engine accepted it while its own gate_summary read stage 0/1, acceptance FAIL
> , accepted_count 0 - a sibling CORRECTION.md now sits beside it carrying the false sentence, the falsifying data, what remains true, and the lesson; THE ARTIFACT IS NOT REWRITT
EN (inv 12). F2, the auditor's claim that the gate's own provenance contradicted the log, is DISPROVED by the exact command it asked for having no shell: git show --stat puts t
he four diagnostic fields and the brief in 676362b (the reviewed tree) and the H2 note fix in a64779d - the hashes were swapped in the reading; recorded in the register anyway,
> because a trail showing only surviving findings is not a trail. MF-A/MF-B/F6 -> U225 OPENED: the check name and the OWED text describe a synthesis the MOCK ConductorAdapter pe
rformed (legs.conductor mock, synthesized_by a fixed literal); disclosed in words in the evidence report and the addendum, RENAME DEFERRED because it edits a product path and w
ould void a green receipt for wording. MF-D -> U226 OPENED: round-2 must-fix MF2 was compressed to a count and its text exists NOWHERE in the tree - unrecoverable; the rule set
> is that reviewer findings are preserved verbatim, never summarized to a number. F4/R1: 3-4 of the 36 checks are static assertions that cannot go red - stated in the evidence r
eport, since stating it in the receipt needs a product edit. F3/F5 folded into U219/U220, deferred for the same receipt-voiding reason. SELF-CHECK, FOREGROUND, MINE: Python 148
> 4, desktop 640, terminal 212 = 2336 green 0 failed 0 skipped; both mutation harnesses ALL CAUGHT with byte-identical restores; hermeticity PASS 54/57 with 3 declared skips; can
onical freeze check OK, no drift in the FROZEN set (--check used deliberately, U222: the advertised regeneration command destroys the operator signature). ARTIFACTS: PHASE17E_E
VIDENCE_REPORT.md, the Phase-17 addendum to FINAL_LIVE_REPORT.md (MF1), the DECISION_REGISTER row (MF4), the register round-3 section, two-commit convention, tags gate/phase-17
> e AND product/fully-live. STATUS COMPLETE per directive s8: all Phase-17 tracks 17A-17E gated, suites green, the final addendum written, the terminal tag applied. THE OPERATOR
IS ADDRESSED ONCE, in FINAL_LIVE_REPORT.md's Phase-17 addendum, and is told FIRST that product/fully-live names a COMPOSITION and NOT a closed owed register - directive s16's p
remise is not met, this track opened U213-U226, and U116-U119 / U210-U212 carry forward. Operator-reserved and not owed defects: the I-V2 TTS reversal, cloud Kimi/Qwen authoriz
ation, and the v1 naming promotion.",

```

```

> Error - two catch clauses on one try - in op12-acceptance-selfcheck.js, with EVERY SUITE GREEN, found only when the packaged Electron run hard-timed-out at 600 s with no receipt.
> t. Nothing headless loads those modules (main.js calls app.whenReady() at load and cannot be required in a test), so the whole selfcheck directory sat outside every syntax check.
> k this repo runs - D-P16-0's own lesson reproduced inside the files that exist to enforce it. selfcheck-guards.test.js now PARSES every file with vm.Script and LOADS every module.
> le-shaped one; reverting the fix turns the suite red (U291). Carried MINORS named in U292 rather than fixed in a high-stakes remediation window. SUITES ON THE TAGGED TREE, FOREGROUND: python 1947 passed / 1 skipped (py -3.12), desktop 692, terminal 216, 17 mutations all RED with byte-identical restores and the harness's own Node scoring PROVED again.
> t a selector that collects nothing (SETUP-FAIL, not RED), both falsification harnesses ALL CAUGHT with byte-identical restores, pyflakes clean, freeze check OK. NO LIVE CALL AND NONE POSSIBLE. NOT DONE AND NOT CLAIMED: no OP-12 live probe has ever executed, no pane has ever been opened for either provider, no OP-12 lease has ever been taken, and NO S overaign node is registered for either - the gate did NOT close on U227 being answered. OPERATOR RULING RECEIVED DURING THIS UNIT: OP-12.1 was appended to AUTONOMOUS_BUILD_DIRECTIVE.md section 17.1 while this unit ran - U227 resolved by SUCCESSOR SCHEMA node@1.1 beside the frozen @1.0 (frozen files never edited, manifest extended ADDITIVELY honoring U222's hand-preserved operator signature), and, since 18C closed with skip-with-record, the remaining work sequenced as phase-18d: the amendment, real registration of both providers, and every 18C leg previously skipped on the registration fence. It is committed VERBATIM as the operator wrote it and THIS UNIT DID NOT ACT ON IT - by the ruling's own instruction the OP-12.1 decision row is the first bookkeeping act of the unit that executes it. product/multi-frontier is deliberately NOT applied: Phase 18's terminal tag belongs to 18D. NEXT UNIT IS phase-18d, HIGH-STAKES, and its first act is the OP-12.1 register row.",
139 | "2026-08-01 iter112: phase-18d.amendment FINISHED - the sub-step is DONE and both mandatory reviewers have now run on it (prior-turn work c40c1e3, remediation 1751384, evidence/registers 75f7751). gate/phase-18d does NOT exist and this unit did not create it. 18D IS SPLIT INTO TWO NAMED SUB-STEPS (directive s3 allows a named sub-step as a work unit for a large phase): (1) .amendment [THIS UNIT, done] the OP-12.1 successor schema, the additive freeze-manifest extension, and the derived registry vocabulary; (2) .close [NEXT, HIGH-STAKES] register both providers as Sovereign nodes, re-run the 18C legs previously skipped on the registration fence (entry conditions UNCHANGED and still the operators - each CLI's own login plus their own edit to the never-committed config/live_operation.json, unset => skip-with-record), whole-track gate-validator + spec-auditor, docs/evidence/PHASE18D_EVIDENCE_REPORT.md in Directive s6 format, the D-P16-0 in-Electron receipt, the gate row, and a SUCCESSOR tag only (s17.1: product/multi-frontier is never moved). RECONCILIATION AT ENTRY: tags said gate/phase-18c was latest and state said next_step phase-18d, which AGREED - no reconciliation commit owed; but HEAD was ONE commit ahead of state.last_commit (8e2cebb -> c40c1e3) because the turn that did the amendment work committed it and died before running a single review or writing state (print-mode, D-LOOP -2 - the same shape as iterations 105, 108 and 110). So this unit ran the reviews that turn owed, on the tree it left. REVIEWS, FOREGROUND, IN-TURN, CONCURRENT, ON c40c1e3: gate-validator PASS_WITH_RESERVATIONS (0 BLOCKING, 1 MAJOR, 3 MEDIUM, 6 MINOR, 4 NIT) after 27 mutations, 23 RED - it re-ran every suite and reproduced every headline number exactly, and it independently reproduced U293 on this Windows host by reverting sorted_files() and running the tool for real (A97DD85C... and operator_signature reset to PENDING), then confirmed the fix reproduces 8E604CA3... with the signature intact; spec-auditor PROHIBITED DRIFT NONE, no invariant violated (3 MEDIUM, 6 MINOR, 5 NIT), with its full statement of the seventeen invariants it checked and found clean, and an honest statement of what it could NOT verify without a shell. EVERY BLOCKING, MAJOR AND MEDIUM FIXED IN-UNIT, each with a red-able test, all nine re-unnable from tools/mutation/_op18d_amendment_mutations.py (9 RED / 9, every restore byte-identical). Findings and dispositions written down in docs/evidence/PHASE18D_AMENDMENT_CHECKPOINT.md because subagent output does not survive a print-mode turn (U226) - and because the DECISION_REGISTER's OP-12.1 row had already shipped CITING that file, which no commit had produced (validator MEDIUM-1 / spec-audit M-2, a permanently dangling citation in an append-only register). THE ONE TO REMEMBER, found by both independently: the work commit claimed the stale "U227 is operator-reserved / no record can exist" prose was corrected "in all nine places it lived", and SEVEN MORE were still there. Three had become flatly false - including a docstring saying the amendment "could never pass for either provider and never will" (a prediction about an operator decision, written by the app) sitting fifty lines above text the same commit corrected in the same file, and the operator-facing run_frontier_providers.ps1 help. A hand-count is not a mechanism; tests/unit/test_u227_prose_is_not_stale.py is one: a live surface may carry a pre-ruling claim only in the company of OP-12.1, checked on the FLATTENED text because the first draft scanned lines and a wrapped sentence defeated it. Against the pre-fix blobs it catches all ten sites; against the tree it is clean; and it caught its own harness the moment the mutation battery moved into tools/. SECOND, MOST OPERATOR-FACING: config/live_operation.example.json - the file an operator reads while deciding to authorize live operation, whose own comment cites invariant 1 - still told them the vocabulary was unchanged and no schema-valid record could name either provider. All three clauses false since the ruling. THIRD: amendment attribution was ASSERTED AND NEVER AUTHENTICATED (spec-audit M-3) - AMENDMENT_AUTHORIZATIONS is free text and nothing checked the cited ruling existed, so a successor schema plus an invented "OP-13.2\'' plus a NODE_SCHEMA_VERSIONS row would have widened the canonical node vocabulary with every check green and no operator act behind it; attribution_for() now requires the ruling id to be findable in the directive or the decision register and fails closed to UNATTRIBUTED. It authenticates the CITATION, not the DOCUMENT: that AUTONOMOUS_BUILD_DIRECTIVE.md is covered by no hash while CLAUDE.md and the hooks are is U294, OPERATOR-owned, and not not fixable here because putting it in EXTRA would move freeze_integrity_sha256 and reset the operator's signature - the exact U222 failure the amendment block was designed around. FOURTH: the SHIPPED OWNED block had no red-able test - replacing provider_node_record with "a Sovereign node record EXISTS for both providers and the 18C legs are unblocked" left all three suites green, because the rules ran only at in-Electron emit time and every test asserted against a synthetic fixture (U296). ALSO FIXED: --check publishes two integrity hashes it never verified and never compared the recorded authorized_by, so a recorded amendment could be re-labelled under another ruling invisibly; the U293 ordering fix was pinned at one of its three call sites; _schema_adapter_enum() had no product caller while every test asserted on it, so widening it left the FENCE untouched (deleted, tests re-pointed at the function register() actually calls); the re-declaration check covered 4 of 11 enum members; ADAPTER_EXEMPTIONS - the one path that widens the node vocabulary with no ruling and no manifest trace - was asserted only incidentally inside a test about ollama_local; node@1.1's description claimed enforcement register() does not perform; and the unattributed-amendment test never planted a file nor ran --check though its docstring said it did. A DEFECT THIS UNIT CAUSED AND CAUGHT BEFORE COMMITTING: Python's write_text on Windows rewrote four files entirely in CRLF, including schemas/node_schema@1.1.json, in a repo whose every tracked file is LF - and --check PASSED, because the manifest had just been regenerated from those same CRLF bytes, so the hash and the file agreed with each other and would have disagreed with every fresh clone (the U274 class). The tell was git's own warning at git add, not any test; all four normalised to LF and the manifest regenerated. SUITES THIS TURN, FOREGROUND: python 1993 passed / 1 skipped (py -3.12; bare python on this host is 3.14 and cannot collect), desktop 695, terminal 216, falsify + authority all mutations caught with byte-identical restores, pyflakes clean on every touched file, freeze check OK with freeze_integrity_sha256 still the Phase-0 8E604CA3... and operator_signature still SATISFIED_BY_OPERATOR_RULING after a regeneration forced by a second, independent edit. NO LIVE CALL AND NONE NEEDED - the operator's switch cites OP-6, so both OP-12 providers are DENIED; nothing was spawned and nothing outlived the unit (D-LOOP-1). NOT DONE AND NOT CLAIMED: no node record for either provider has been created, no OP-12 lease has ever been taken, and the 18C legs skipped on the old fence are still skipped. The vocabulary is open; nothing is wired to write into it. That is phase-18d.close.",
140 | "2026-08-01 iter113: gate/phase-18d CLOSED and TAGGED, and product/multi-frontier APPLIED - PHASE 18 COMPLETE (work 2a351e7 + 03d78db + cdc45c, evidence/registers 56fecc4, tags gate/phase-18d + product/multi-frontier). RECONCILIATION AT ENTRY: tags said gate/phase-18c was latest and state said next_step phase-18d.close, which AGREED - no reconciliation commit owed; HEAD 1583823 was the state-writing commit itself and the tree was clean, so unlike iterations 105/108/110/112 no prior turn had died mid-unit and this one owed no reviews on someone else's tree. THE WIRING, which is what .close was: provider_node_registration.py turns a GovernedProbeSession into a node@1.1 record - built from the session and the adapter that would run, validated by the REAL jsonschema validator against the REAL file, registered through the REAL NodeRegistry onto the REAL hash-chained append-only log, and CLOSED (spawn->transition->exit) when the session ends. `registrar` joins profile_loader and operator_terms_confirmed as a REQUIRED keyword of governed_probe_session because whether a session becomes a Sovereign node is the caller's fact; None is legitimate and means exactly no record; node_registered is a MEASUREMENT now, not the hardcoded False it was through 18C. Registration is step 7 and is NOT a gate - a refused registration refuses the session and hands the lease back, because a leased supervised terminal with no record is the naked-but-leased session the chain exists to prevent. MEASURED IN ELECTRON on this host (PHASE18D_REGISTRATION_SELFCHECK.json, ok:true, source cdc45c == HEAD, tracked product tree clean): both providers registered, allowance 1 each ASSERTED not displayed, chain verified, records TERMINATED, four fences refusing (unadmitted adapter / unsupervised session / not-spawned-by-supervisor / concurrent log holder), and the operator's world unmoved - switch still OP-6, 0 sessions, 0 leases, ledger by byte-identical, grok 0/1 agy 0/1 painted. REVIEWS, FOREGROUND, IN-TURN, CONCURRENT (D-LOOP-2): gate-validator PASS_WITH_RESERVATIONS after 13 mutations of its own, an independent

> the Bash tool's 600 s ceiling, so run it in background and POLL it to completion in-turn (D-LOOP-2).",
146 | "2026-08-02 iter118: phase-18e.close FINISHED - gate/phase-18e is TAGGED, product/multi-frontier-v2 applied as a SUCCESSOR (product/multi-frontier never moved, s17.1), Phas
> e 18 and OP-12.2 are COMPLETE, and the one thing 18E could not do is a keystroke that belongs to the operator (work 4061230 + b901d60 + 737f6db + f5f0c3f, evidence/registers cd
> 08878). Both mandatory reviewers ran FOREGROUND, in-turn, CONCURRENTLY - TWICE. RECONCILIATION AT ENTRY: tags said gate/phase-18d + product/multi-frontier were latest and state
> said next_step phase-18e.close, which AGREED - no reconciliation commit owed; HEAD f76e0b6 was the state-writing commit and the tree was clean, so no prior turn had died mid-u
> nit. THE FIRST ACT WAS TO ASK THE WORLD, NOT THE REGISTER: whether the operator had cleared U317 (both OP-12 CLIs' own directory-trust modal) is not knowable from a file, so th
> e leg was re-run live. They had not; four more live in-Electron runs across this unit all stopped in the same place, and ZERO live exchanges were spent because a gated leg stop
> s before a prompt is drawn. THE GATE CLOSES AS SKIP-WITH-RECORD (D-P18-13) and the reasoning is recorded rather than dressed up: s17's skip-with-record clause enumerates TWO en
> try conditions and BOTH are met - the trust modal is a THIRD, discovered in flight - so applying that clause is an ANALOGY, not a citation; s6's substitution is PARTIAL because
> nothing stands in for a live answer; s8 yields neither of its BLOCKED categories; and s17.2(1)'s live-exchange criterion is recorded UNMET, with the tag certifying the govern
> d path and not a model's reply. ROUND 1: gate-validator FAIL (2 BLOCKING, 2 MAJOR) and spec-auditor PROHIBITED DRIFT NONE with 2 MAJOR - and they converged INDEPENDENTLY on the
> same thing for the THIRD time in this track: the gate-closing report asserted in the PAST TENSE three acts that had not happened (the reviews themselves, the FINAL supplement,
> the tags) and pre-committed its own verdict. Iteration 115's inversion was in a field, 117's in a receipt's prose, this one in the document that closes the gate. The other BLO
> CKING was arithmetic: the report and the .live.electron checkpoint counted THREE live runs where the operator's durable node log carries FOUR (the unreported 06:52:44Z run - U
> 322, closed by a CORRECTION file beside the never-edited checkpoint. ROUND 2, on the remediation: gate-validator PASS_WITH_RESERVATIONS (\\"no BLOCKING or MAJOR remains\\"; it re
> computed the whole 79-row hash chain itself with the log writer's own hasher, beyond what the receipt checks) and spec-auditor PROHIBITED DRIFT NONE with 3 MAJOR ON THE FIXES -
> each real: the FINAL supplement said \\"both providers answered live\\" (the operator's probe) while its own terminal section said no model ever had, and U311's WITHDRAWAL of th
> e grok acceptance had never reached the operator-facing document; the \\"every sink that now exists\\" absolute survived in two summary lines while s17.2(1)'s PTY-transcript sink
> is a SECOND unmet element (U324 - what exists is the alternate-buffer SCREEN, which keeps no scrollbar); and the supplement's own operator command would have OVERWRITTEN the
> receipt a published checkpoint cites by content - U322's cause, unfixed, handed to the operator as an instruction. All three fixed. THE RULE TOOK THREE VERSIONS AND THE THIRD I
> S RIGHT: a late consent gate may explain only a leg that NEVER TYPED. Round 1 keyed on echo; round 2 keyed on SUBMISSION and the auditor showed submission cannot happen without
> an echo in this check, so the rule could not fire and the residual route (typed, never echoed) was PINNED GREEN by a test. Typing is the act that creates the ambiguity: from o
> utside, a modal that ate the keystrokes and a live session that took them and said nothing are identical, and picking the flattering reading is how a U310 disappears. CREDENTIA
> LS GOT STRICTER, NOT JUST BETTER DOCUMENTED: the check used to READ any real credential value the host had set so it could restore it - s2.2 and OP-12 s13 forbid reading, not o
> nly storing - so a name the host already sets is now SKIPPED entirely, and U321(d) is CLOSED with a dated note. RECEIPTS ARE RUN-STAMPED NOW (...<unit>.<UTC>.json", never ove
> rwritten), which is what actually fixes U322 rather than describing it, and which makes the operator's own re-run safe. VERIFIED on the tagged tree: pytest 2208 passed / 1 skip
> ped in 368.92s, apps/desktop 820, terminal 216, mutations 34/34 RED with byte-identical restores (11/11 on .live.shape - the 2026-08-01 register row's \\"8/8\\" corrected in the
> .close row), freeze check OK, final receipt source.commit f5f0c3f with a clean tracked product tree BEFORE and AFTER the live sessions ran with this repo as their ConPTY cwd. D
> -LOOP-1: leases 1->0 per provider on every run, durable ledger leases:[], sessions before === after === 0, no electron/grok/agy process surviving. WHAT IS OWED AND BY WHOM: U31
> 7 is the operator's, one keystroke per CLI ('grok', 'agy', answer the trust prompt, let them exit, re-run 'node apps/desktop/selfcheck/run.js op12-live-acceptance --unit operat
> or-run'); U312's live-budget overrun on .live.shape is the operator's to rule on and this gate added nothing to it; U310 (grok's headless -p exits zero saying nothing) stays
> untested on the interactive channel and U311's withdrawal stands, so grok_build has NEVER verifiably answered this build by any path while google_antigravity has answered once,
> headless. STATUS COMPLETE: OP-12.2 named 18E the last owed leg, every executable part of it is done, and the remainder is operator-reserved - so the loop addresses the operato
> r once, in FINAL_LIVE_REPORT.md's Phase-18E supplement, and stops. TRAPS THAT STILL HOLD for whoever picks this up: pytest must be 'py -3.12' NOT 'python' (3.14 here, 86 collec
> tion errors that look like broken code); do not rewrite repo files with pathlib.write_text (LF->CRLF - use io.open(newline='')); compound 'cd && git' writes need approval on th
> is host, so 'cd' first in its own call and then 'git commit -F- -- <paths>'; env-var prefixes and ';' -chained commands are refused, so pass options as flags ('--unit') instead;
> and the op12-live-acceptance launcher's own timeout is 1500 s, longer than the Bash tool's ceiling, so run it in background and POLL it to completion in-turn (D-LOOP-2).",
147 | "2026-08-09 iter119: phase-19.1 FINISHED - the OP-13 revert is done, U327 is settled by RESTORING the plan pin, and both mandatory reviewers ran FOREGROUND in-turn CONCURRE
> NTLY TWICE (work c5078bf, remediation 0f81a6e, round-2 close ff62897). gate/phase-19 does NOT exist and this unit did not create it; product/multi-frontier-v2 was never moved.
> RECONCILIATION AT ENTRY: tags said gate/phase-18e + product/multi-frontier-v2 were latest and state said next_step phase-19.1, which AGREED - no reconciliation commit owed; HEA
> D 6c27868 was the resume commit and the tree was clean, so no prior turn had died mid-unit and this one owed nobody's reviews. WHAT THE OPERATOR RULED, DONE: ANTIGRAVITY_HEADLE
> SS_MODE is 'plan' again with the DELETED comment restored verbatim (not a new one), the antigravity_execution carve-out is gone AND SO IS THE execution_profile PARAMETER (a key
> word a caller can pass is the re-arming surface), the 18A probe path reverted with it because an unconditional guard would otherwise make the operator's own diagnostic refuse i
> ts own argv, and TestTheGuardHasNoExecutionProfileCarveOut refuses accept-edits across five argv spellings x six profiles plus the TypeError leg. U327 SETTLED BY EVIDENCE, NOT
> PREFERENCE: the two live receipts the deleted comment cites are still on disk and still say both plan and default were accepted:false, so the widening buys no measured behaviou
> r; the justification that replaced the comment ('default is the installed CLI's normal execution mode') is absent from the grok --help capture, which enumerates the modes WITHO
> UT ranking them. --no-plan went back on the forbidden list with it: the capture reads 'Disable plan mode', so beside the restored pin it is that pin's cancellation under a seco
> nd name. THE REVIEWERS EARNED THEIR KEEP, TWICE. Round 1: gate-validator FAIL + spec-auditor 4 MAJOR, both independently finding the SAME residue - the launch-ticket NOTE still
> advertised '--mode accept-edits' and 'plan disabled' because the untagged range had edited that prose to match the argv it widened, and 2262 tests could not see it (U341). Fix
> ed by DERIVING the note from the argv. The spec-auditor also argued the --allow mcp__sovereign__ * rule (U340, which this unit had opened as keep-and-record) should be REVERTED

```

```
> not kept - the flag is 'Permission allow rule' on the installed capture, D-P18-13 is about the class not one enum, and its defence rested on policy role checks U326 says are no
> t in place. ACCEPTED AND REVERTED; U340 carries both calls and why the second won. Round 2 on the remediation: gate-validator PASS, spec-auditor PROHIBITED DRIFT NONE / no MAJO
> R - but the note deriver FAILED OPEN (an inclusion list could not over-claim yet could silently OMIT, and the flags it would have omitted are --allow and --no-plan; the validat
> or proved it, all 2272 stayed green), so it is an EXCLUSION list now with the reverse direction asserted. EVIDENCE: mutation harness 8 rows -> 12 -> 14, 14/14 RED, restores byt
> e-identical; full suite 2262 -> 2272 -> 2275 passed, 1 skipped, ~10.5 min each, plus two independent validator re-runs. The harness's blanket 'every row restores b109f02 bytes'
> claim was overstated for four rows and is now precise - the same class of defect this unit exists to correct. ALSO CLOSED: .grok/config.toml no longer ships permission_mode='d
> efault' (this build was shipping the node-controlled config its own restored comment names as the threat). OPEN AND OWED, honestly: U341 (claudex/codex notes still prose, unit 1
> 9.10), U342 (nothing has OBSERVED that an OP-12 pane's Sovereign MCP attachment survives the allow-rule removal - an owed measurement on the first live pane leg, not a reason t
> o restore the rule), and the whole of U326/U328-U339 which belong to units 19.2-19.10. NEXT: 19.2 - route the twelve inline role checks in mcp_server/collaboration_service.py t
> hrough control_plane/policy.py (invariant 7), with the falsification the unit spec demands: a mutation to a policy rule must be caught by a test that goes through the collabora
> tion path. Note for that unit: it is the fix U340's reverted justification depended on, and U342's live measurement waits behind 19.3.",
148 | "2026-08-10 iter120: phase-19.2 CHECKPOINTED, NOT CLOSED - the U326 delegation is built, measured and registered, and it owes ONE more review round. RECONCILIATION AT ENTRY
> : tags said gate/phase-18e + product/multi-frontier-v2 were latest and state said next_step phase-19.2, which AGREED - no reconciliation commit owed. BUT the tree carried work
> from a DEAD PRIOR TURN: two committed work commits (9c59cb0 the delegation, 3e5b4dd the round-2 remediation) that LOOP_STATE did not know about, plus an UNTRACKED evidence draf
> t whose s5.3 and s7 were placeholders waiting for a round-3 review that, under D-LOOP-2, was dead. This unit re-ran everything fresh and foreground. ROUND 3 (on 3e5b4dd): gate-
> validator FAIL 1 BLOCKING + spec-auditor PROHIBITED DRIFT NONE / 2 MAJOR. The BLOCKING was the unit spec's own falsification requirement: the validator wrote its OWN probe and
> FIVE policy rules survived the full suite unpinned (message_read short-circuiting for directing roles; debate_read admitting the opener; the candidate rule admitting conductor;
> a member added to ROLES; deleting round 2's own record_synthesis task-read). Fixed in 65ae5f6 with five tests and rows P16f-P16i, P26 -> 34/34 RED. ROUND 4 (on 65ae5f6): gate-
> validator FAIL 3 BLOCKING + spec-auditor 1 MAJOR. All five round-3 survivors confirmed RED - and THREE MORE of the SAME CLASS survived the whole 2329-test suite: _DIRECTING_ROL
> ES admitting VOICE (one word, four authorities, invariant 25), authorize_debate_close admitting the debate's OPENER (a worker may open one, then close it with its own decision)
> , and authorize_open_debate's subset absorbing the CALLER (a gate names itself into any task's debate). FOUR consecutive rounds, four sets of unpinned MEMBERSHIP SETS behind pi
> nned deny statements, each round pinning what the last one found. So round 4's fix is NOT three more tests: 3fa401a pins the WHOLE VERDICT SURFACE - every admitted role x every
> collaboration operation, 136 cells, through CollaborationService, as one table no single-constant widening can pass (U352, recorded as a METHOD for the next authority surface)
> . 37/37 RED. THE OTHER MAJOR, found by the spec-auditor twice: the register rows the evidence AND FIVE TRACKED SOURCE FILES said existed (U343-U349) did not exist - the registe
> r ended at U342 - so every 'recorded rather than fixed' disposition was uncollateralized. Written now: U343-U352 (8ac5bf4). WHAT IS OWED, and it is the whole reason this is a C
> HECKPOINT: the round-4 remediation POST-DATES round 4, so directive s18's fix-after-validation-voids-it applies. ROUND 5 IS THE NEXT UNIT'S FIRST ACT - gate-validator + spec-au
> ditor, foreground, concurrent, on 3fa401a + 8ac5bf4 - and 19.2 is done only when a round returns with nothing whose fix changes the tree. If round 5 finds a SIXTH instance of t
> he membership-set class, that is evidence about U352's COVERAGE and belongs in U352, not in a sixth patch. VERIFIED THIS UNIT: pytest 2331 passed 1 skipped (1845 unit + 486 res
> t, split because the suite runs ~10 min against a 600 s per-command ceiling); mutation harness 37/37 RED restores byte-identical; u326_before_after 19 of 34 differ; apps/desktopo
> p 836 pass; terminal 216 pass. ZERO live provider calls - nothing here needs one. NO tag created or moved (gate/phase-19 does not exist; product/multi-frontier-v2 still points
> at cd08878). DELETED .gv3_scratch/ - the dead turn's mutation scripts wrote into control_plane/policy.py without taking .mutation-lock and with no restore handler, and the roun
> d-3 spec-auditor caught one of their widenings SITTING IN THE TREE while suites ran; those suite numbers were discarded and re-taken clean. TRAPS FOR THE NEXT TURN: pytest is `
> py -3.12`, never `python` (3.14 here, 86 collection errors that look like broken code); the full suite EXCEEDS a 600 s command timeout - split it; and never run a mutation harm
> ess concurrently with a suite or a reviewer, which is how iteration 120 lost its first set of numbers.",
149 | "2026-08-10 iter121: phase-19.2 CLOSED. ROUND 5 was this unit and it was the checkpoint note's standing order - gate-validator (own git worktree, so its mutation probe coul
> d not be read mid-flight) + spec-auditor (main tree, read-only), FOREGROUND, IN-TURN, CONCURRENT, on 3fa401a + 8ac5bf4. RECONCILIATION AT ENTRY: tags said gate/phase-18e + prod
> uct/multi-frontier-v2 were latest and state said phase-19.2.close, which AGREED - no reconciliation commit owed; HEAD 021e279 was the state-writing commit and the tree was clea
> n, so unlike iterations 105/108/110/112/114/120 no prior turn had died mid-unit and this one owed nobody's reviews. VERDICTS: gate-validator FAIL (1 MAJOR, documentation-only)
> - and it explicitly did NOT find a sixth instance of the four-round membership-set class: it re-attacked ROLES, _SCOPED_ROLES and _DIRECTING_ROLES with its own spellings in BOT
> H directions and every one went RED. Its own 16-mutation probe: 10 RED, 2 equivalent mutants, 1 confirmation of U351(b), and 4 REAL SURVIVORS of the ADJACENT class - a rule key
> ed on an input the matrix would never puts in front of a policy call (_unknown admitting an extra name; task status COMPLETED; debate state CLOSED; message kind decision), all
> four green against all 2331 tests. spec-auditor: PROHIBITED DRIFT NONE, 0 BLOCKING, 1 MAJOR - U350 says the invariant-18 case is 'pinned in the matrix' and it is pinned NOWHERE
> (_open_then_close always posts turns as W1/W2, so no cell has a directing role that both argued and closed; the fix moves zero cells). Both converged: NO code-behaviour change
> required. SO THE UNIT ENDS THE WAY IT SHOULD HAVE STARTED - 4bbd84e changes docstrings and comments ONLY (no statement, expression, constant, signature, control-flow line or a
> ssertion), and the two findings that would need CODE (U355 authorize_debate_turn has no role clause so a voice participant may post debate turns, invariant 25; U354 the invaria
> nt-18 closer) are RECORDED, NOT PATCHED - iteration 120 set that rule for the membership class and it is applied by EXPLICIT extension to the adjacent one, because patching eit
> her moves matrix cells, which voids round 5 and buys round 6 on the tread that produced rounds 2,3,4,5. THE LESSON, and it is the whole unit: the defect was never in the author
> ity code - it was documentation asserting absolutes the code falsifies, and it recurred INSIDE THE FIX FOR ITSELF. A third review (read-only delta validation of the uncommitted
> correction) returned FAIL: the new policy.py sentence denied a delta the evidence records, the new test-docstring sentence was false for ROLES, and it cited U353/U355/U356 whi
> le the register ended at U352. A fourth read-only pass then truth-checked the repaired prose AND the six new rows and found SIX MORE false sentences, all in rows written that s
> ame turn (a generator that cannot re-emit; an 'each' false for 2 of 4 widenings; a true conclusion on a false reason; a widening claim false for the only reachable widening; a
> standing-rule citation that silently broadened its class name; a title saying nine rows contradicted by its own body saying fifteen). All repaired before commit. STOPPING RULE
> ADOPTED AND RECORDED: from round 5 onward a finding whose repair would change the tree goes to a register row, not a patch - that bounds the regress without softening anything.
> MEASURED THIS UNIT, all foreground, on the final tree: pytest 2331 passed 1 skipped (1845 unit + 478 integration + 8 security/recovery/evaluation - THREE-way split now, integr
> ation alone is 594 s against the 600 s ceiling); mutation harness 37/37 RED restores byte-identical; u326_before_after base=b529314 19 of 34 differ; apps/desktop 836 pass; term
> inal 216 pass (both re-run on THIS tree, not attributed). ONE FAILURE, NOT HIDDEN: the first integration run returned 1 failed 477 passed - test_opencode_candidate_live, taken

1 | """Task-scoped operational collaboration over Sovereign's existing durable store.
2 |
3 | Same contract as `memory_service.py`, and for the same reason: **every ROLE OR SCOPE decision
4 | is asked of `control_plane.policy` (I-M2 delegation, invariant 7 – MCP is access, not
5 | authority).** This module makes no role or scope decision of its own: it validates shapes,
6 | enforces lifecycle legality, persists, and raises whatever reason the policy hands back. The
7 | rules about *who* live one package over, where the operator can change them once for this package.
8 | (Not once for the product: `apps/desktop/main.js` holds a fourth, DIVERGENT copy for the Electron
9 | control surface – stricter in one place, ungated in another – U345, which no Phase-19 unit owns.)
10 |
11 | Until Phase 19 unit 2 that was not true here. The policy was accepted in the constructor and
12 | never read, while fifteen role/scope decisions were made inline (cold audit finding B1 named
13 | twelve of them; U326) – a second copy of the authority, free to diverge from the one memory
14 | operations obey.
15 |
16 | Phase 19 unit 5 changed HOW those writes reach the store, not who may make them (U330). Every
17 | writer that reads a record and writes a successor now computes that successor inside the store's
18 | `BEGIN IMMEDIATE` boundary, from the row read there, through `mutate_operational_task` /
19 | `mutate_operational_debate`; the two creators use `create_operational_*`, which refuse to
20 | overwrite. Five of the seven used to build a successor from a Python-side snapshot and blind-write
21 | it back, so two live workers posting to one debate lost a turn with no error and no conflict
22 | record. The rules that depend on record CONTENT – the bounded-round ceiling, the close quorum –
23 | moved inside the fence with the write they guard, and each asks the policy again on the row it
24 | actually acts on.
25 |
26 | One consequence, stated because the mutation harness measured it rather than assumed it: the
27 | `state != "OPEN"` checks that remain BEFORE each debate transaction are early guards, not the
28 | guarantee. Deleting one changes no observable refusal – the in-fence check raises the same
29 | sentence – so they are graded by nothing on their own. They are kept for message ORDER (a caller
30 | sending a malformed decision to a closed debate still hears "debate is not open" first, as it
31 | always did) and because refusing before opening a write transaction is cheaper. The load-bearing
32 | copy is the one inside the mutator, and the racing tests in
33 | `tests/unit/test_operational_write_path.py` §2 are what hold it there.
34 |
35 | What is deliberately still here, because it is legality rather than authority – the same split
36 | `memory_service.py` has always had with `mcp_server/lifecycle.py`: the bounded-debate round
37 | limit and budget range, the "a debate may not close without a turn from every participant"
38 | quorum, the "synthesis requires candidates from every worker" completeness rule, the
39 | `debate is not open` state gate, the referential checks that a candidate names only messages
40 | and debates that exist, and the CANDIDATE-status check. They are recorded as U344 so the
41 | boundary is argued in the open rather than assumed; none of them asks who the caller is. The
42 | CANDIDATE-status check is the closest call and U344 says so: it is the SHAPE half of a rule
43 | whose *who* half lives at `control_plane/policy.py:authorize_publish` ("workers may publish
44 | only CANDIDATE entries"), so it can drift from its twin even though it never reads a caller.

1  """Memory service: the server-enforced memory lifecycle over the store (Plan section 9.4).
2
3  Ties together three separated concerns without absorbing any of them:
4  - persistence (SovereignStore + CAS): immutable versions, CAS heads, conflict records;
5  - lifecycle legality (lifecycle.py): which status edges are legal at all;
6  - authorization (control_plane.policy): who may publish/promote – the AUTHORITY.
7
8  Every write path asks the policy first (I-M2 delegation) and advances the head by CAS
9  (D-MCP-03), so a losing concurrent writer gets a conflict record, never a silent overwrite.
10 The logical key for a fact is its entry_id; versions are entry_id@N; the head points at the
11 current version.

1 | """Loopback wire protocol + client for the Sovereign MCP server (Plan section 4.4; U6).
2 |
3 | Transport decision (U6, recorded): the official Python MCP SDK is not installable under the
4 | build's network prohibitions (pip is out of scope; only npm + vendor-doc reads are allowed),
5 | so Phase 3A implements a minimal newline-delimited JSON request/response protocol over a
6 | loopback TCP socket. The server is a genuinely separate OS process bound to 127.0.0.1. The
7 | resource/tool op set mirrors Plan section 9.5; swapping in the MCP SDK later is an adapter
8 | change behind this client.
9 |
10 | Fail-closed: a disconnected client raises McpDisconnected; callers must checkpoint locally
11 | and refuse shared-memory-dependent work rather than proceed on stale state (F5).
12 |
13 | ONE narrow exception, added at Phase 17B `.legs`: a connection the SERVER has already closed is
14 | re-established before the next request is written (see `_drop_if_peer_closed`). Nothing has been
15 | sent at that point, so this cannot re-apply anything – it is a reconnect, not a retry of applied
16 | work. Every other disconnect, and in particular a LOST RESPONSE, still fails closed exactly as
17 | above, because a delivered request may already have been applied.

97 |     def _drop_if_peer_closed(self) -> None:
98 |         """Discard a socket the SERVER has already closed, BEFORE anything is written to it.
99 |
100 |         U60's root cause (found at Phase 17B `legs`): `MCPServer`'s handler carries `timeout = 60`
101 |         so idle threads cannot linger (F6). A live `claude` worker call runs longer than that, so
102 |         while the model is thinking the server reaps the caller's connection. Writing into that
103 |         socket then SUCCEEDS – the FIN is unread and the bytes land in the local send buffer – and
104 |         the failure surfaces on the READ as `WinError 10053`, where retrying is forbidden because a
105 |         delivered request may already have been applied. So the send-side retry below never fires,
106 |         and the governed run degrades: exactly what the first `legs` live dispatch did.
107 |
108 |         Checking BEFORE the write is what makes the recovery safe rather than a guess: nothing has
109 |         been sent, so re-establishing cannot re-apply anything. This only ever discards a connection
110 |         the peer has finished with – a healthy idle socket is neither readable nor errored, and this
111 |         returns without touching it.
112 |
113 |         It NARROWS the window; it does not close it. A reap landing between this check and the
114 |         `sendall` below restores the old behaviour – the write succeeds into a FIN'd socket and the
115 |         read fails closed. That outcome is correct (a possibly-applied request is never retried), it
116 |         is just not recovered. Note the structural consequence: with a live worker call bounded at
117 |         420 s against the server's 60 s handler timeout, EVERY live dispatch is reaped at least once
118 |         and relies on this reconnect. That is a workaround for a timeout mismatch, not a resolution
119 |         of it – recorded rather than papered over.

308 |
309 |     What this replaces: two hardcoded fields, `gemini_contribution` and `grok_contribution`,
310 |     both required. A task worked by any other set of nodes – two Codex workers, a Claude worker
311 |     beside a local Ollama one, one worker, three – could not be synthesised, and the only way
312 |     to comply was to file a node's work under a vendor name that was not its own. Work is
313 |     dispatched by capability descriptor and reported by node identity (I-SC1); a fixed pair of
314 |     vendor slots is neither.
315 |
316 |     The cross-check runs in both directions, mirroring the closed-debate gate above, because
317 |     the two-slot form could fail in neither: a contribution naming a node that published no
318 |     candidate is refused (invented work), and a candidate node the caller left out is refused
319 |     (dropped work). Both refusals name the node, because a conductor that must guess which one
320 |     it got wrong will guess.
321 |
322 |     Returned in candidate order, so the record is stable for the CAS hash regardless of the

357 | def _considered_debates(self, task_id: str, raw: Any) -> tuple[list[str], list[str]]:
358 |     """The closed-debate gate, computed from the TASK's debates rather than from the caller's
359 |     list (U332).
360 |
361 |     The gate used to be `for debate_id in debate_ids: ...` – a loop over an argument, so an
362 |     empty list satisfied it vacuously and a conductor could publish a synthesis over a debate
363 |     that was still being argued simply by not mentioning it. Naming a CLOSED debate from a
364 |     different task passed too, because `get_debate` is project-scoped. Four rules replace it,
365 |     and the first is the one U332 is about:
366 |
367 |     * no debate on this task may still be OPEN – named or not;
368 |     * every id the caller names must belong to this task, and be CLOSED;
369 |     * every CLOSED debate on this task must be named – omission was the bypass;
370 |     * ABORTED debates (U416) are reported separately, from the store, so a deliberation that
371 |     never concluded cannot be presented as one that did, and cannot block the task forever.
372 |
373 |     `_nonempty_strings` therefore applies exactly when there is something to skip. A task that
374 |     never needed a debate stays synthesizable; nothing is being waived, because the
375 |     cross-check – not the list's length – is what closes the hole.
376 |
377 |     One coupling, recorded rather than hidden (U411): the debates are read through
378 |     `list_debates`, which filters by `authorize_debate_read`. That is correct – the tool layer
379 |     must not read past the authority – and today it is exhaustive, because only the directing
380 |     roles reach here and `_SCOPED_ROLES` does not contain them. If debate-read scoping ever
381 |     narrows for a directing role, an unreadable debate becomes an invisible one, and this gate
382 |     weakens silently.

1  """Governed live-Codex spawn path – the ONE place a live `openai_codex_cli` terminal is born.
2  Phase 15C `.adapter` (directive $11 track 15C; register OP-6).
3
4  The second live frontier provider the operator authorized (OP-6). This is the real supervisor/
5  startup path the directive requires to enforce, at the actual spawn site and before any live call,
6  every entry condition for live operation. It is deterministic, fail-closed permission logic
7  (Buildout Directive $4) – never model output – and mirrors frontier_spawn.py (`claude_code`)
8  exactly so the two live providers share one governed shape.
9
10 Order of gates (all must pass; any failure => no live spawn):
11  1. `ProfileLoader.assert_startup([cap], live_auth)` – whole-roster profile eligibility AND the
12  LIVE_OPERATION_AUTHORIZED gate, driving the REAL endpoint.
13  2. `LiveAuthorization.assert_provider_live("openai_codex_cli")` – the primary gate re-asserted at
14  the live-spawn site (belt-and-suspenders; distinct call site from the roster check).
15  3. R8 $6 operator live-terms confirmation – the `[OPERATOR]`-flagged item from
16  R8_TOS_VERIFICATION_OPENAI_CODEX.md $6 (the wrapped-orchestrator ToS interpretation). In a
17  non-interactive session it is unmet => skip-with-record (directive $10.4).
18  4. `codex` CLI actually present on the host (real backend only; a mock proof injects its backend
19  and skips this).
20  5. SubscriptionGovernor.acquire – I-X3, concurrency governed by the enforced authorization
21  (OP-6: at most 2 terminals/subscription, read from live_auth; a config may narrow to 1).
22  Only then is a supervisor-issued AdapterContext constructed (spawned_by_supervisor=True) and handed
23  to the live adapter. If construction fails the terminal is released (no wedged count).
24
25  The credential itself is never touched here or in the adapter ($2.2): the `codex` CLI holds its own
26  ChatGPT-subscription OAuth token in a host-native store (`~/codex/auth.json`).

1  """Governed conductor-first pane – the ONE place the LIVE interactive CONDUCTOR chat pane is born.
2  Phase 15E `conductor-pane` (directive §13 / OP-8; §12.4 conductor-first startup).
3
4  `pane_node_spawn.spawn_node_from_selection` REFUSES the conductor role and points here: the conductor
5  is not a worker handle under a "conductor" badge – it is the conductor-first, pinned, succession-capable
6  pane 1 the operator lands in on launch and *talks to* (OP-8 §13). This module produces that GOVERNED
7  pane, reusing the frontier live-gate set verbatim (a live conductor pane is a subscription-backed live
8  path exactly like a live worker) and differing only in what it builds:
9
10     * an INTERACTIVE `claude` launch (`build_interactive_command` – NO `-p`; the operator drives it),
11       not the one-shot `claude -p --output-format json` worker command;
12     * the CONDUCTOR chrome: pinned pane 1, model badge = the current SELECTION (fable-5 / recorded
13       fallback), `attended` mode (the operator types into it);
14     * the Resume→Select succession affordance reachable from that chrome (invariant 28 / OP-8 §13.7).
15
16  Order of gates (all must pass; any failure  no conductor pane):
17  1. `ProfileLoader.assert_startup([claude_code cap], live_auth)` – roster eligibility AND the
18     LIVE_OPERATION_AUTHORIZED gate (keyed on the PROVIDER capability, never on the selection label).
19  2. `LiveAuthorization.assert_provider_live("claude_code")` – the primary live gate re-asserted.
20  3. R8 §6 operator live-terms confirmation – `[OPERATOR]`-flagged; unmet  fail-closed refusal.
21  4. `claude` CLI present on the host (real launch only; a mock launcher injects its own session).
22  5. I-X3: register the authorized allowance, then acquire this pane's ONE subscription terminal;
23     release on any construction failure so the count never wedges.
24
25  Honesty (invariant 3, §6/§10.4): the badge shows the operator SELECTION label ("fable-5"); the
26  EXECUTING checkpoint stays unverified until a live reply reports one (`bind_conductor_selection`). This
27  module builds and gates the interactive session but makes NO live call itself – the actual interactive
28  ConPTY drive is an operator-run surface like every GUI in this build (directive §6 substitution). A
29  mock-first `launcher` proves the whole governed path with zero live calls; a real interactive launch
30  supplies a real launcher through the identical path and is torn down within its unit (D-LOOP-1).
31
32  Out of scope for THIS sub-step (kept honest, not faked): native-MCP orchestration – the conductor
33  dispatching to worker CLIs while conversing (OP-8 §13.4) is `.objective`; voice-IN (§13.5) is `.voice`;
34  restart recovery of the conductor-first layout is `.recovery`.

1 | """Governed live-conductor spawn path – the ONE place a LIVE `claude_code`-backed conductor is
2 | born. Phase 15B `.conductor` (directive §11 15B: "make the backend conductor-capable").
3 |
4 | The conductor is an INTERFACE + runtime selection (invariant 3, current selection Fable 5). This
5 | module binds the LIVE claude_code backend (via `ClaudeCodeConductorBackend`) into the Phase-4
6 | `ConductorAdapter` behind the SAME governed contract used for the live worker terminal – no naked
7 | session (I-C1/invariant 2), no credential handling (§2.2), no self-authorization of any protected
8 | action. It reuses the live-frontier gate set from `frontier_spawn` verbatim (a live conductor is a
9 | subscription-backed live path exactly like a live worker), differing only in the adapter it builds.
10 |
11 | Order of gates (all must pass; any failure no live conductor):
12 | 1. `ProfileLoader.assert_startup([claude_code cap], live_auth)` – roster eligibility AND the
13 |    LIVE_OPERATION_AUTHORIZED gate, evaluated on the *provider* capability (`adapter="claude_code"`)
14 |    because live authorization is keyed on the provider, never on the conductor selection label.
15 | 2. `LiveAuthorization.assert_provider_live("claude_code")` – the primary live gate re-asserted.
16 | 3. R8 §6 operator live-terms confirmation – `[OPERATOR]`-flagged; unmet skip-with-record.
17 | 4. `claude` CLI present on the host (real backend only; a mock proof injects its own backend).
18 | 5. `SubscriptionGovernor.register_subscription(..., allowance=live_auth.terminals_for(provider))`
19 |    – the ConductorAdapter itself acquires/releases the terminal at start()/close() (Phase-4
20 |    design), so this path only sets the authorized allowance and never double-counts.
21 |
22 | Mock-first: `attempt_live_conductor_smoke` drives the whole path with an injected mock backend and
23 | publishes a real CANDIDATE decision through MCP; the single LIVE `claude` conductor smoke stays
24 | skip-with-record until the operator terms are discharged (directive §10.4). No live call here.

1  """Process-tree containment scaffold: Windows Job Objects (Plan section 7-P3, invariant 29).
2
3  What this ENFORCES today (no admin rights needed): every process assigned to the job –
4  including grandchildren it spawns – is killed when the job handle closes
5  (JOB_OBJECT_LIMIT_KILL_ON_JOB_CLOSE). A node cannot leave surviving process trees.
6
7  What this does NOT enforce (recorded, U10 / Phase 10): filesystem or network denial at
8  the OS layer. Until P10 hardening, fs containment is the WorkspaceBinding API layer and
9  network policy is the (future) broker; a raw-syscall bypass is out of this phase's scope.

1  """Live-gate ingredients for the two OP-12 frontier providers – Phase 18B `.picker`.
2
3  The `claude_code` and `openai_codex_cli` panes get theirs from `frontier_spawn` / `codex_spawn`,
4  each of which also owns a HEADLESS terminal-spawn function. These two providers have no headless
5  spawn function to own (`FrontierProviderCliBackend.generate` refuses while `_LIVE_SPAWN_PATH_WIRED`
6  is False – U268), so this module carries only what the INTERACTIVE pane authorization needs:
7
8  * the `AdapterCapability` the profile/live gate evaluates – the same object shape, so
9  `ProfileLoader.assert_startup` treats these as real live paths with no per-provider branch;
10 * a presence exception PER PROVIDER, because operator directive §14 says provider-specific
11 failure messages must identify the ACTUAL provider and one provider's error text must never be
12 printed for another. A shared `FrontierCliUnavailable` would have made that a convention held by
13 whoever wrote the message; two types make it a property of the code.
14
15 Deliberately NOT here: a `spawn_grok_terminal` / `spawn_antigravity_terminal`. Through 18B/18C the
16 reason was categorical – a headless terminal for these providers needs a Sovereign node record, and
17 `NodeRegistry.register` refused both adapter ids while U227 was unrulred. **OP-12.1 (2026-08-01)
18 ruled it: `node@1.1` admits both, so the registry no longer refuses.** The functions are still not
19 here, and the reason is now narrower and worth stating exactly: nothing has been WIRED to create
20 those records yet – that is phase 18D `.close`, together with the 18C legs that were skipped on the
21 old fence. Adding the spawn functions ahead of the wiring would be a path that looks live and is
22 not, which is the same mistake in a different place.

1 | """Governed live-frontier spawn path – the ONE place a live `claude_code` terminal is born.
2 | Phase 14B `.adapter` (directive §10.1; register OP-4/OP-5).
3 |
4 | This is the real supervisor/startup path the directive requires to enforce, at the actual
5 | spawn site and before any live call, every entry condition for live operation. It is
6 | deterministic, fail-closed permission logic (Buildout Directive §4) – never model output.
7 |
8 | Order of gates (all must pass; any failure => no live spawn):
9 |   1. `ProfileLoader.assert_startup([cap], live_auth)` – whole-roster profile eligibility AND
10 |      the LIVE_OPERATION_AUTHORIZED gate (discharges the .liveflag MINOR-2 latent-enforcement:
11 |      a test drives THIS real endpoint).
12 |   2. `LiveAuthorization.assert_provider_live("claude_code")` – the primary gate re-asserted at
13 |      the live-spawn site (belt-and-suspenders; distinct call site from the roster check).
14 |   3. R8 §6 operator live-terms confirmation – the `[OPERATOR]`-flagged dated-terms items. In a
15 |      non-interactive session these are unmet => skip-with-record (directive §10.4).
16 |   4. `claude` CLI actually present on the host (real backend only; a mock proof injects its
17 |      backend and skips this).
18 |   5. SubscriptionGovernor.acquire – I-X3, concurrency governed by the enforced authorization
19 |      (OP-6: at most 2 terminals/subscription, read from live_auth; a config may narrow to 1).
20 | Only then is a supervisor-issued AdapterContext constructed (spawned_by_supervisor=True) and
21 | handed to the live adapter. If construction fails the terminal is released (no wedged count).
22 |
23 | The credential itself is never touched here or in the adapter (§2.2): the `claude` CLI holds
24 | its own OAuth token in a host-native store.

1 | """Governed OpenCode spawn path – the ONE place a supervised OpenCode coding harness is born.
2 | Phase 14C `.harness` (directive §9 table 14C; §10.2).
3 |
4 | The local-harness analogue of node_runtime/supervisor/frontier_spawn.py. It enforces, at the
5 | actual spawn site and fail-closed (Buildout Directive §4 – deterministic, never model output),
6 | every entry condition for a supervised OpenCode terminal:
7 |
8 | 1. **Presence gate** – the `opencode` CLI is present/spawnable (probe.present). Absent   refuse
9 |   (`OpenCodeUnavailable`), no naked fallback.
10 | 2. **Version gate** – the probed version parses AND meets the minimum. Unparseable/too-old
11 |   refuse (`OpenCodeVersionError`). This is the directive's "presence/version gate".
12 | 3. **Supervised identity (invariant 2 – no naked session)** – a supervisor-issued permission
13 |   profile is required; a missing profile   `NakedLaunchRefused`. Only then is a
14 |   supervisor-issued `AdapterContext(spawned_by_supervisor=True)` constructed. The eventual
15 |   coding adapter (`.worktree`) is a `ModelWorkerAdapter`, whose base contract independently
16 |   refuses any non-supervisor context.
17 |
18 | Deliberately ABSENT here, and why (recorded honesty, not an omission):
19 | - **No `LIVE_OPERATION_AUTHORIZED` gate.** That gate governs live *frontier/subscription*
20 |   providers (directive §10.1); OpenCode + Ollama are local, credential-free, and authorized by
21 |   §10.2 directly – so the frontier live-flag does not apply.
22 | - **No `SubscriptionGovernor`.** Local-model terminals are never subscription-bounded
23 |   (subscription_governor.py) – I-X3 governs frontier subscriptions only.
24 | - **No credential handling (§2.2)** and **no paid path (§2.3)** – enforced in the harness's
25 |   `build_env` (scrubs every provider key) + the `ollama/*`-pinned run command.

1  """Governed node spawn FROM a per-pane picker selection (Phase 15E `spawn`; OP-7 §12.2/§12.3).
2
3  The per-pane picker (`control_plane/nodes/pane_picker.py`, sub-step `picker`) only OFFERS
4  options. This module is the SPAWN dispatcher: it turns exactly ONE selected option
5  (provider × model × role) plus a mode (attended | autonomous) into a supervised, governed
6  spawn – or a fail-closed refusal – and produces the pane chrome the shell renders.
7
8  It is a THIN, deterministic coordinator (Buildout Directive §4 – permission/lifecycle logic,
9  never model output). It does NOT re-implement any gate; it composes the existing, already-gated
10 supervised spawn paths so there is exactly one place each kind of terminal is born:
11
12 * frontier `claude_code` → `frontier_spawn.spawn_claude_code_terminal` (I-X3 governed)
13 * frontier `openai_codex_cli` → `codex_spawn.spawn_codex_terminal` (I-X3 governed, per-role)
14 * local `ollama_local` → `ResidencyPlanner.request_load` (invariant 22 – visible VRAM
15 residency) then a supervised local node: `opencode_spawn.spawn_opencode_harness` for a
16 coding role, else a supervised `LocalWorkerAdapter` (reasoning). Local terminals are NEVER
17 subscription-governed (subscription_governor.py governs frontier subscriptions only).
18
19 Fail-closed selection validation (all BEFORE any spawn path or governor/planner mutation):
20 * an `available=False` (greyed) option is refused – the picker already recorded WHY it is
21 unavailable, and a node the operator cannot see offered must never be born;
22 * a role not in the option's offered `roles` is refused (I-SC1 – capability is chosen from
23 what the descriptor offered, never inferred from the model name);
24 * an unknown mode is refused;
25 * a missing node identity OR permission profile is refused (invariant 2/29 – no naked session;
26 the downstream adapter/harness enforce the same guard as defense-in-depth);
27 * a frontier selection with no subscription_ref is refused (an uncounted terminal defeats I-X3);
28 * a local selection with no ResidencyPlanner, or a model with no registered footprint, is
29 refused (we never schedule VRAM we cannot ADMIT – admission is against an unverified
30 budget, never a proof of fit; U96).
31
32 Attended vs autonomous (OP-7 §12.3): BOTH modes spawn through the SAME supervised path with the
33 SAME permission profile – the mode is a chrome/routing label, NOT an authority grant (invariant
34 1: an operator-attended node gains no privilege the profile did not already grant). The full
35 interactive ConPTY attachment is a later sub-step (`conductor-pane`); here the mode is carried
36 as a first-class governed fact.
37
38 D-LOOP-1: `GovernedSpawn.teardown()` releases a frontier terminal's I-X3 count so a spawn made in
39 a work unit is released within it; it is idempotent and a no-op for a local (ungoverned) node.
40
41 Mock-first: frontier paths take an injected mock backend and local coding takes an injected mock
42 harness/probe, so the whole dispatch is proven with zero live calls; a real live spawn supplies a
43 real backend/harness through the identical path and must be torn down within the unit.

1  """A governed OP-12 provider session becomes a Sovereign node RECORD – Phase 18D `.close`.
2
3  **What this closes.** Invariant 2 says every terminal is a Sovereign node. Through 18C the two
4  OP-12 providers could not be one: `node@1.0`'s `adapter` enum is frozen and has no member for
5  `grok_build` or `google_antigravity`, so `NodeRegistry.register` refused them and the refusal was
6  the honest answer (U227). The operator ruled U227 on 2026-08-01 – **OP-12.1, by successor schema**
7  – and 18D `.amendment` shipped `schemas/node.schema@1.1.json` beside the untouched frozen file.
8  That opened the vocabulary and deliberately wired nothing to it: the amendment's own evidence says
9  "the vocabulary is open; nothing is wired to write into it." This module is the wiring.
10
11  **It is one direction only.** Registration is not a gate and must never become one – the schema
12  says so in `node@1.1`'s own description, and it is worth repeating where the code is: a node record
13  is what a session that ALREADY passed the live switch, the operator's terms determination, CLI
14  presence and the I-X3 lease leaves behind on the append-only log. Registering does not authorize
15  anything. What it does is make the session auditable after the fact: the record carries the
16  adapter, the subscription it was counted against, the workspace it was bound to, and – from the
17  registry itself – WHICH version of the canonical vocabulary admitted it, so a reader can tell a
18  `node@1.0` node from one the OP-12.1 amendment admitted without re-deriving enums from a log that
19  does not carry them.
20
21  **Three refusals, all fail-closed, all auditable:**
22
23  1. a session whose own `supervised` field is not True is refused HERE, before anything is
24  written – the registrar reads the session's claim, it never makes it on the session's behalf
25  (I-C1). The registry's own `spawned_by_supervisor` guard is downstream of this one and stays;
26  2. a record that does not validate against the schema version it names is refused by the real
27  jsonschema validator against the real file on disk – including an `adapter` no version admits
28  and a `schema` string pointing at a version that does not exist. Unreadable file refusal,
29  never a skipped check;
30  3. the registry fence itself (`registry.py`) still refuses an adapter id in NO node schema
31  version, with the append-only `registration_refused` event it has always written. `kimi_k3`
32  is the live example and stays OWED-pending-operator.
33
34  **The log is durable operator state, not repository content.** It lives under `.sovereign_store/`
35  beside the terminal-lease ledger – gitignored, per-host, hash-chained, append-only (invariant 12).
36  A record written for a session that then exits is CLOSED on that same log (`transition` → `exit`),
37  because a one-shot probe that leaves a node reading SPANNING forever is a D-LOOP-1 leak in the one
38  place an auditor would look for it.

1 | """The governed, supervised session a HEADLESS one-shot OP-12 provider call runs inside –
2 | Phase 18C `.probe-path`, discharging **U234**.
3 |
4 | 18A built the one harmless live probe (`GROK_PROVIDER_OK` / `GEMINI_PROVIDER_OK`) and then refused
5 | to execute it: the child would have been a bare `subprocess.run` holding no node identity, no I-X3
6 | subscription lease and no teardown accounting – a naked session (invariant 2 / I-C1). While the
7 | providers sat outside every code-pinned live scope that refusal was academic. **18B `.scope` ended
8 | that** by adding the OP-12 row, which is exactly what U237 needed and which left the
9 | `_SUPERVISED_PROBE_PATH` constant as the only thing between `Action probe` and an unsupervised
10 | frontier CLI. The 18A round-4 validator's ruling was explicit: opening the operator's switch before
11 | this path exists is *a gate failure at 18C*. This module is that path.
12 |
13 | **It is the interactive pane's gate chain, in the same order, for a headless child.** Nothing here
14 | is a second, looser rule – that is the whole point, because a probe that could be permitted by a
15 | weaker rule than a session is a bypass with a diagnostic's name on it. The first cut of this module
16 | *claimed* that parity and did not hold it, in the two places a caller supplies rather than the
17 | module decides: it manufactured `ProfileLoader(DeploymentProfile("cloud"))` when none was injected,
18 | so invariant 20's air-gap half could never refuse (an air-gapped host opened a leased session), and
19 | it defaulted the operator's R8 §6 determination to *confirmed*. Both are now **required keywords**,
20 | exactly as `worker_pane_spawn._authorize_frontier` has them, and
21 | `test_the_gate_chain_matches_the_pane_path` pins the sequence so the claim cannot drift away from
22 | the code again. The chain:
23 |
24 | 1. `ProfileLoader.assert_startup([capability])` – roster eligibility + `LIVE_OPERATION_AUTHORIZED`
25 | (invariant 20, fail closed by absence); the loader is the CALLER's, built from the host's real
26 | `SOVEREIGN_DEPLOYMENT_PROFILE`, because a profile this module picks for itself is not a gate;
27 | 2. `LiveAuthorization.assert_provider_live` re-asserted at the authorization site;
28 | 3. the R8 §6 **operator** live-terms determination (OP-9 class; invariant 1 – never ours to make);
29 | 4. CLI presence, with **that provider's own** exception type and a RESOLVED binary, never a bare
30 | name for the child to PATH-search (operator directive §14);
31 | 5. **I-X3**: the durable `TerminalLeaseLedger` is projected into a `SubscriptionGovernor`, so a
32 | terminal the operator's shell holds is counted here, and this probe takes ONE lease on its own
33 | provider's resource (`grok_build_subscription` / `google_antigravity_subscription`, allowance 1
34 | each, never merged – operator directive §12). That is also the mechanism behind §17's "do not
35 | attempt simultaneous same-provider sessions": it is refused, not merely discouraged.
36 | 6. the lease is released on **every** exit path, and the release is **measured** into
37 | `teardown_record` rather than asserted (D-LOOP-1).
38 |
39 | `supervised_probe_runner` is the execution half: the child runs inside the repository's managed-
40 | process boundary (`process_tree.run_managed_process` – a Windows **job object** on the operator's
41 | host, a POSIX process group elsewhere; the deterministic suite runs on both), it must be the same
42 | file the gate resolved (`argv[0] == session.executable`, refused otherwise – the gate below
43 | resolves a binary precisely so the child cannot be a different one), it carries no interactive
44 | stdin, and the credential-bearing environment is removed by NAME (§2.2/§13 – names, never values)
45 | with its working directory bound to the authorized workspace. Descendants (grok's leader/agent
46 | helpers) are reaped rather than left behind, and – because a containment failure is the one thing
47 | this boundary exists to detect – `ProcessTreeCleanupError` is REPORTED into the verdict and into
48 | `teardown_record["process_tree_clean"]` rather than escaping as a crash the operator would read as
49 | a broken tool (invariant 27/29).
50 |
51 | Honest note on "no interactive stdin": `supervised_probe_runner` passes `stdin=subprocess.DEVNULL`,
52 | and `process_tree.run_posix` honours it directly. On Windows the job-member shim owns the handle
53 | (it needs a pipe for its own GO admission) and hands `sys.stdin` to the real target, so the child
54 | inherits a pipe that `communicate()` has already closed – EOF, the same *behaviour*, by a different
55 | mechanism than the argument names. Recorded as U281 rather than described as a closed handle.
56 |
57 | **The node record – the 18D `.close` wiring, and its exact limits.** Through 18C this module
58 | registered no Sovereign node RECORD and could not: `NodeRegistry.register` refused both adapter ids
59 | because node@1.0's `adapter` enum is frozen and has no member for either (U227). OP-12.1
60 | (2026-08-01) ruled U227 by successor schema, `node@1.1` admits both, and 18D `.close` wires the
61 | registration: a caller-supplied `registrant` (required keyword, `None` permitted and meaning exactly
62 | "no record") writes a validated `node@1.1` document on the append-only node log once the terminal
63 | is held, and the record is CLOSED on every exit path. `node_registered` is now a MEASUREMENT.
64 | Registration is step 7 and not step 0 on purpose: it is not a gate, it authorizes nothing, and a
65 | caller that registered a node without walking this chain would get none of the checks above –
66 | which is why the record is written last, from a session that already passed all of them.
67 |
68 | **What it still is NOT.** The job object does not make the CLI's own behaviour trustworthy:

```

```

69 | `--permission-mode plan` / `--mode plan` are arguments the harness honours, and invariant 29 says
70 | never trust the harness (U25 remains owed). What the boundary does guarantee is process-tree
71 | teardown on every exit path. And an interactive PANE still mints only an identity – `worker_identity`
72 | creates no record, and wiring that path is not this module's to do (U297).

499 |     """A `frontier_provider_recon.Runner` that executes the child under supervision.
500 |
501 |     Same boundary the live `claude_code` backend uses: a managed-process boundary that owns the
502 |     whole descendant tree (a Windows job object on the operator's host; a POSIX process group
503 |     elsewhere), so a CLI which spawns helpers (grok's leader/agent processes) cannot leave any
504 |     behind when this returns OR times out – operator directive $12's process-tree termination on
505 |     every exit path. No interactive stdin reaches the child (see the module docstring's note on the
506 |     Windows mechanism, U281), because an inherited non-TTY stdin lets a TUI-capable CLI block
507 |     forever and turns a probe into a timeout.
508 |
509 |     **The child is the file the gate resolved.** `argv[0]` must equal `session.executable`, or this
510 |     refuses. Without that line the gate's "refuse to spawn a bare binary NAME" rule protected a
511 |     value nobody spawned: the runner executed whatever argv it was handed, and the two agreed only
512 |     because one call site happened to pass the same string.
513 |
514 |     Returns the runner protocol's `(exit_code|None, stdout, stderr, timed_out, spawn_error)` – a
515 |     timeout, a missing binary and a CONTAINMENT failure are REPORTED, not raised, so the probe's
516 |     acceptance logic classifies them (exit-code-first: an exit-0 transcript is never reclassified by
517 |     its text). `ProcessTreeCleanupError` in particular: it is the one signal this boundary exists to
518 |     produce, and letting it escape turned an invariant-29 containment failure into a traceback that
519 |     the PowerShell runner reports to the operator as "a tool failure, not a governed refusal"."""

1  """Subscription concurrency governor (I-X3; Plan §18.2).
2
3  One active terminal per subscription/account by default. The supervisor consults this
4  before spawning a frontier (subscription-backed) node: a spawn against a subscription
5  already at its allowance is refused with a visible reason. Local-model terminals are not
6  subscription-bounded and are never governed here. Succession must release the predecessor
7  terminal before the successor claims it (release() then acquire()).
8
9  Deterministic and fail-closed: the recorded allowance defaults to 1 and is only raised on
10 an EXPLICIT operator-authorized value passed by the caller – never on inference or silence.
11 The caller (the supervised spawn path) reads that value from the enforced
12 `LiveAuthorization.terminals_for(provider)` – the PER-PROVIDER allowance, which is the
13 narrower of the operator's config value and that provider's own code-pinned cap; it is
14 never a governor default.
15
16 OP-6 (2026-07-19, register OP-6): the operator raised the per-subscription allowance to at
17 most **2 terminals**. The governor enforces that as a HARD CAP here (`MAX_ALLOWANCE`): a
18 `register_subscription` call requesting more than 2 is REFUSED – a defense-in-depth so no
19 caller can widen concurrency past the operator ruling even by accident. The cap is
20 governor-owned and reversible; raising it again requires a new operator authorization and a
21 code change here, never a config value.
22
23 OP-12 (2026-07-31, register OP-12; operator directive s12): two FURTHER subscriptions –
24 `grok_build_subscription` and `google_antigravity_subscription` – at allowance **1 each**,
25 never merged with each other or with the OP-6 pair. That ceiling is read from the single
26 authority that records it (`live_authorization.provider_terminal_cap`) and is enforced here
27 together with a ref-to-provider binding, because a per-provider cap that a second ref
28 spelling can sidestep is not a cap.
29 """
30 from __future__ import annotations
31
32 import threading
33 from dataclasses import dataclass, field
34
35 from control_plane.profiles.live_authorization import (
36     ANTIGRAVITY_PROVIDER,
37     GROK_PROVIDER,
38     provider_terminal_cap,
39 )
40
41 # OP-6 hard cap: the governor never grants more than 2 terminals on one subscription,

47     """The hardest ceiling this provider can be registered at, in the governor's own terms.
48
49     ONE table, not two. The first version of this function kept its own `PROVIDER_MAX_ALLOWANCE`
50     map "as defense in depth" – but the two tables had OPPOSITE fail directions (the authorization
51     table answers 0 for an unrecorded provider, this one answered 2), so a future provider added to
52     the live scope and to the authorization cap while being forgotten here would have inherited a
53     governor ceiling of 2 and the second layer would have defended nothing. Duplication that can
54     disagree is not depth, it is drift (invariant 30; spec-audit MEDIUM-4 / MAJOR-3).
55
56     So the per-provider ceiling is read from the single authority that records it, and the layering
57     that IS real stays: this function still clamps to the governor-owned `MAX_ALLOWANCE`, and the
58     check happens again at the durable ledger. A provider with NO recorded per-provider cap
59     (`mock`, local adapters, anything not subscription-scoped) falls back to the global cap – those
60     are not subscription-backed and never reach an I-X3 refusal by this route."""

1 | """Durable I-X3 terminal leases – the count that outlives the process that took it.
2 |
3 | Phase 17A `lease` (directive §16 track 17A). `SubscriptionGovernor` is an IN-PROCESS counter: every
4 | bounded emitter in this build creates one, acquires, and releases at teardown (D-LOOP-1). That was
5 | correct while no live terminal outlived its emitter. 17A ends that: the CONDUCTOR pane runs a REAL
6 | interactive `claude` session inside the shell's ConPTY, owned by the long-lived Electron process,
7 | gated by a short-lived Python emitter. If the count died with the emitter, I-X3 would be decorative –
8 | the shell could hold two sessions while every emitter reported 0/2.
9 |
10 | This module is the durable half: a small, file-backed, cross-process lease ledger.
11 |
12 | * **Authority stays where it is.** The ledger COUNTS; it does not authorize. The allowance is
13 | passed in by the caller from the enforced `LiveAuthorization.terminals_for(provider)` (the
14 | per-provider allowance, itself code-pinned per authorizing register row), and the governor's
15 | `MAX_ALLOWANCE` hard cap, its per-provider cap and its ref-to-provider binding are all
16 | re-asserted here as defense in depth – a widened caller cannot buy a further terminal by
17 | passing a bigger number, and cannot buy one by inventing a second ref spelling either.
18 | * **Fail closed on the count, open on the corpse.** Over-allowance `SubscriptionLimitExceeded`,
19 | no mutation. But a lease whose HOLDER PROCESS IS DEAD is reaped: a crashed shell must not wedge
20 | the operator's own subscription forever. Liveness is a pid check, injectable for tests.
21 | * **Counting state only (§2.2).** A lease record is identity + pid + timestamp + purpose. No env,
22 | no argv, no token, nothing credential-bearing is ever persisted or returned.
23 | * **A corrupt ledger fails closed and is never silently reset** – resetting would fabricate a zero
24 | count and hand out a terminal the operator may already be using.
25 |
26 | Concurrency: every mutation is a read-modify-write under an exclusive lock file
27 | (`O_CREAT|O_EXCL`, bounded spin), and the ledger is written via a temp file + `os.replace` so a
28 | reader never observes a half-written document. A lock is broken only when its recorded owner pid is
29 | GONE (age is the fallback for a pid that was never written) – an age-only rule lets two writers each
30 | unlink the other's fresh lock and silently lose an acquire. Sufficient for the writers this build
31 | has on one host; it is not a distributed lock and does not pretend to be.
32 |
33 | A lease is keyed to `(subscription_ref, node_id, session_id)` (schema `@1.1`, Phase 17A `.pty`,
34 | closing U75). The conductor NODE id is a constant (`conductor-pane-1`), so node-only keying counted N
35 | real interactive sessions as ONE terminal – latent while nothing launched, load-bearing the moment the
36 | shell can spawn. `session_id` is the identity of the ConPTY session that will hold the terminal;
37 | sessionless (``) leases keep the old node-level idempotence for the not-yet-launched case, and a
38 | `@1.0` ledger written by an older process is read as sessionless rather than rejected.
39 |
40 | KNOWN LIMITS, recorded rather than implied away: release performs no ownership check, so the durable
41 | cap binds cooperating local callers, not a hostile one; and pid recycling is not defended against.
