1  """Governed LIVE WORKER pane – the ONE place an interactive worker session is authorized from a
2  picker selection. Phase 17B ``ticket`` (directive §16 track 17B; OP-7 §12.2/§12.3; closes the
3  authorization half of **U70**).
4
5  The operator's first-use finding F3: choosing a model on a pane "records + badges but launches
6  nothing". 16B was honest about that (``governed:false``, ``selected_awaiting_governed_spawn``) – the
7  selection went through the guard and stopped. This module is the worker analogue of
8  ``conductor_pane_spawn``: it turns ONE picker option (provider × model × role × mode) into an
9  executable, governed, INTERACTIVE launch spec – or a fail-closed refusal.
10
11  Why a separate module from ``pane_node_spawn.spawn_node_from_selection``: that dispatcher builds a
12  HEADLESS handle (a ``ModelWorkerAdapter`` / OpenCode harness the scheduler drives). A pane the operator
13  watches and types into needs the other shape – argv for an interactive CLI the shell spawns in a
14  ConPTY. Both apply the SAME selection guard (``assert_selection_spawnable``, extracted so the two can
15  never drift on greyed/mode/role/naked refusals); this path is then STRICTER, refusing the coding
16  roles it has no isolated worktree to give (below) – stricter, never laxer.
17
18  Gate chain, by locality:
19
20  * **frontier** (every id in ``FRONTIER_PANE_ADAPTERS``: ``claude_code``, ``openai_codex_cli``, and
21  since 18B ``picker`` the OP-12 pair ``grok_build`` + ``google_antigravity``) – the identical live chain the conductor pane
22  runs: ``ProfileLoader.assert_startup``[capability], live_auth`` (roster eligibility AND the
23  LIVE_OPERATION_AUTHORIZED / air-gap gate, invariant 20) → ``assert_provider_live`` → R8 §6 operator
24  terms → CLI presence → I-X3 ``acquire`` on the subscription. A refusal at any step releases nothing
25  it did not take, and ``teardown()`` hands the terminal back (D-LOOP-1).
26  * **local** (``ollama_local``) – NOT subscription-governed (invariant 19: locality is per-node; the
27  subscription governor governs frontier subscriptions only) and credential-free. What governs it
28  is invariant 22: the model MUST route through the ``ResidencyPlanner``, which refuses an unsized or
29  over-budget model, and this path additionally refuses one that would only fit by DISPLACING a
30  model the Ollama daemon is already serving – the planner is a bookkeeping mirror, it does not own
31  the host's VRAM, and "never mid-generation eviction" cannot be enforced against a ``generating``
32  flag that the host seeding never sets. The residency state is carried into the chrome so
33  "loading" is never displayed as "ready", and the BUDGET's provenance travels with it. The budget
34  is ALWAYS ``estimate:true`` – an operator-supplied ``SOW_VRAM_BUDGET_MB`` is a figure some process
35  stated, not a queried GPU capacity, so it is a stand-in with a better source, not a measurement.
36  ``budget_source`` says which. No authorization here ever claims the fit was proven (spec-audit
37  MINOR-2, 2026-07-26: the previous wording implied ``estimate:false`` was reachable; it is not).
38
39  Honesty rules this module will not bend:
40  * the chrome badge's LABEL and ``model_verified`` are carried verbatim from the picker option
41  (invariant 3) – ``model_verified`` is never upgraded here, only a live reply can do that. The
42  ``model_slug`` is deliberately NOT verbatim: it is the id the CLI was probed to accept, which can
43  differ from the label's spelling (``fable-5`` → ``claude-fable-5``), and both are shown;
44  * a requested slug that is not available resolves to the CLI default and is RECORDED as a fallback
45  (``is_fallback``, directive §11 15B) – never silently substituted;
46  * this module makes NO live model call and reads NO credential: it builds argv, counts terminals
47  and reserves VRAM. The ConPTY spawn is the shell's, under the authorization this produces.

230 |
231 |     §2.2 in the strictest reading: names, never values – the shell already holds its own environment,
232 |     so a name is all it needs to drop one. The UNION of ALL THREE frontier classifiers (claude,
233 |     codex, and the shared OP-12 one covering `XAI_*` / `GEMINI_*` / `GOOGLE_*` / `ANTIGRAVITY_*` –
234 |     operator directive §13) is used for EVERY worker locality, including local: a superset can only
235 |     over-scrub (a local model needs no cloud credential at all), while a per-provider list would
236 |     leave the other provider's key in the child env of a session that has no business seeing it.
237 |     The OP-12 classifier was added with the providers themselves rather than after: a `grok` pane
238 |     launched before the union included `XAI_API_KEY` would have inherited exactly the variable §13
239 |     names first.
240 |
241 |     `shell_env_names` are the var NAMES the CONSUMER holds, unioned in before classification (U105).
242 |     Measuring the list in the EMITTER's environment and applying it to the SHELL's was sound only
243 |     while the two environments matched – and 17B itself made divergence reachable, because a per-child
244 |     `opts.env` is how the `ticket` self-check scrubs PATH. Two concrete ways the emitter's list can
245 |     miss a key the shell holds: (1) the shell was launched with a credential var the emitter's child
246 |     env does not carry; (2) Windows preserves the CASE a var was created with while this classifier
247 |     upper-cases, so `Anthropic_Api_Key` in the shell and `ANTHROPIC_API_KEY` here classify the same
248 |     but are two different literal keys, and the shell deletes by exact spelling. Names only – a
249 |     caller-supplied entry is never read for a value, and the emitter refuses any `name=value` pair."""

356
357     Phase 19 unit 1, from the gate-validator's MAJOR-1 and the spec-auditor's MAJOR-1 on the OP-13
358     revert. These notes used to be hand-written prose, and the untagged post-18E range edited them
359     to match the widened argv it shipped: `--mode accept-edits` for Antigravity and "plan disabled"
360     for Grok. Reverting the argv alone would have left the launch TICKET – which is what the
361     receipts and the shell surface show the operator – advertising a mode the operator had just
362     forbidden, with nothing in 2262 tests able to see the contradiction, because a sentence cannot
363     disagree with a list it was never derived from.
364
365     So it is derived now, in BOTH directions – and the second direction is the one round 2 of this
366     unit's review had to fix. The first version rendered an ENUMERATED set of noteworthy flags: it
367     could not over-claim, but it could silently under-claim, and the flags it would have omitted
368     include `--allow` and `--no-plan`, i.e. precisely the half of the widening this unit reverted.
369     Disclosure that fails open is not disclosure (gate-validator MEDIUM-1, spec-audit MEDIUM-1 /
370     NIT-9). What is rendered is now every flag in the argv EXCEPT `_NOTE_SILENT_FLAGS`, and
371     `tests/unit/test_worker_ticket_honesty.py` walks it both ways.
372
373     Invariant 27 (the orchestra is visible) and build directive $4: routing rationale is

601 | def _assert_fits_without_displacing(planner: ResidencyPlanner, model: str) -> None:
602 |     """Refuse, WITHOUT mutating the planner, a local pane that could only fit by displacing another
603 |     model (invariant 22).
604 |
605 |     Why this is a refusal and not a scheduled swap: this planner is a bookkeeping MIRROR of the
606 |     Ollama daemon's residency, not its allocator. The host seeding marks models resident but never
607 |     sets `generating`, so the planner's own "evict only idle models" rule is evaluated against a flag
608 |     nothing populates – a model it considers idle may be answering a prompt right now, and invariant
609 |     22 states "never mid-generation eviction" in absolute terms. So a local pane is authorized only
610 |     when it fits in FREE VRAM. Deliberate consequence: on a busy host the operator gets an honest
611 |     "no room" instead of a pane whose birth silently reclaimed VRAM from a model in use.
612 |

```

1  """VRAM residency planner (invariant 22; Plan §18.2, OP-7 §12.2 – Phase 15E `.picker`).
2
3  Invariant 22 in full: *local concurrency is hardware-bounded (8-14B tier); VRAM residency is
4  **scheduled, visible, never mid-generation eviction**.* OP-7 §12.2 makes the same rule a UI
5  requirement: the per-pane model picker enumerates the operator's local models and shows each
6  one's residency state – resident / loading / awaiting-eviction – so swaps are visible and a
7  model that is mid-generation is never yanked out of VRAM to make room for another.
8
9  This module is that scheduler, as a **pure, deterministic, fail-closed** state machine. It
10 holds NO GPU handle and makes NO real VRAM measurement: the total budget and each model's
11 footprint are injected inputs (the host reads them from `ollama ps` / `ollama list` in an
12 operator-run driver – the Phase-1 spike substitution pattern). Everything here is testable
13 without a GPU, and the picker renders exactly the `snapshot()` this produces – no fabricated
14 residency state ever reaches the UI.
15
16 Determinism: eviction order is least-recently-touched first, where "recency" is an internal
17 monotonic counter bumped on every load/touch – never a wall clock (`Date.now()`-class calls
18 are banned in this build and would defeat replay anyway).
19
20 Fail-closed choices (Buildout Directive §4 – deterministic lifecycle logic, never inference):
21 * an unsized model is NEVER scheduled (we cannot prove it fits) – refused, not guessed;
22 * a model larger than the whole budget is refused (can never be resident);
23 * when room can only be made by evicting a **generating** model, the load is NOT forced:
24   the blocking generators are flagged AWAITING_EVICTION (visible) and the new model is
25   QUEUED until they finish – invariant 22's "never mid-generation eviction", enforced in
26   code, not by convention.
27 """

1  """Operational collaboration race WATCHER (test fixture): a third real process that does nothing
2  but read the shared task while two worker processes write it, and reports any moment at which a
3  node's candidate revision went BACKWARDS.
4
5  Why a third process is needed, and why the obvious cheaper checks are not:
6
7  * the FINAL state only reveals a lost update that happened in the last write – measured at
8  1 of 3 runs under a deliberately spliced defect;
9  * a WRITER watching its peer cannot see the damage it does. Each node only ever publishes a
10  higher revision of its own candidate, so what a stale successor destroys is the PEER's
11  revision – and the writer's own pre-transaction snapshot is never older than what it last
12  read, so its view of the peer is monotone whether or not the fence holds. Measured at 2 of 5.
13
14  A reader sampling the durable record between the peer's write and the stale write sees the
15  regression directly. Sampling runs thousands of times a second against a write rate in the tens,
16  so the window is observed rather than raced for.
17
18  python operational_race_watcher.py <db_path> <task_id> <stop_file> [deadline_seconds]
19
20  Prints one JSON result line: every regression observed, how many samples it took, and how many
21  DISTINCT (node, revision) pairs it actually saw – the last of those is what says the watch was
22  live rather than blind, and it exists because the round-2 validator made `regressions == []`
23  vacuous by blinding this loop while both of the parent's other guards still held.
24
25  The deadline is not decoration: this process is spawned by a test and only stops when the parent
26  writes the stop file, so a parent that dies between spawn and stop would leave it spinning
27  (D-LOOP-1 – no orphans). It bounds itself.

1 | """Phase 14B .adapter (integration): the live `claude_code` frontier terminal driven through
2 | the REAL supervisor/startup entrypoint (node_runtime/supervisor/frontier_spawn) and the REAL
3 | MCP server.
4 |
5 | Three things are proven here:
6 | 1. MOCK-FIRST end-to-end: an authorized live_auth + confirmed operator terms + an injected
7 |   MockClaudeCliBackend spawns a governed terminal that reads scoped context from MCP, passes
8 |   the local gate, and publishes a CANDIDATE – the whole governance path, zero live call.
9 | 2. REAL-ENTRYPOINT ENFORCEMENT (discharges .liveflag MINOR-2): the same entrypoint, given the
10 |  REAL in-repo authorization (DENIED-by-absence – config/live_operation.json is gitignored
11 |  and absent), refuses to spawn. Enforcement is at the real spawn site, not just in a test.
12 | 3. I-X3: the subscription governor admits exactly one terminal; a second is refused.
13 | And the single live smoke: attempted through the real path with the real repo authorization ->
14 | skip-with-record (no live call), the honest non-interactive outcome (directive $10.4).

1 | """Phase 15B `conductor`: the LIVE `claude_code` backend is CONDUCTOR-CAPABLE – the Phase-4
2 | ConductorAdapter can bind it behind the same governed contract (no naked session, no credential,
3 | subscription-governed), and the governed live-conductor spawn enforces every live gate.
4 |
5 | Proven here:
6 | 1. `ClaudeCodeConductorBackend` structurally satisfies the `ConductorBackend` contract and so does
7 |   Phase 4's `MockReasoningBackend` – "conductor-capable" is a checkable claim.
8 | 2. `propose_plan` is honest: a JSON decomposition parses to tasks; garbage / malformed NO
9 |   fabricated tasks (fail closed), with the raw excerpt preserved.
10 | 3. MOCK-FIRST end-to-end through the REAL endpoint + REAL MCP: an authorized live_auth +
11 |   confirmed terms + an injected mock backend spawns a governed conductor that loads conductor
12 |   files from MCP and publishes a CANDIDATE decision – zero live call.
13 | 4. Governance: DENIED-by-absence auth and unconfirmed operator terms both skip-with-record; the
14 |   I-X3 allowance comes from live_auth (OP-6: 2), a third conductor on the subscription refused.
15 | 5. The conductor holds NO provider credential; the executing model is recorded honestly.
16 | 6. A `BackendAuthPause` mid-cycle is a fail-closed pause that releases the terminal.

1  """Phase 15C .adapter (integration): the live `openai_codex_cli` frontier terminal driven through
2  the REAL supervisor/startup entrypoint (node_runtime/supervisor/codex_spawn) and the REAL MCP
3  server.
4
5  Proven here (mirrors the claude_code .adapter integration):
6      1. MOCK-FIRST end-to-end: an authorized live_auth + confirmed operator terms + an injected
7         MockCodexCliBackend spawns a governed terminal that reads scoped context from MCP, passes the
8         local gate, and publishes a CANDIDATE – the whole governance path, zero live call.
9      2. REAL-ENTRYPOINT ENFORCEMENT: the same entrypoint, given a DENIED (absent) authorization,
10         refuses to spawn. Enforcement is at the real spawn site, not just in a test.
11      3. I-X3 under OP-6: the subscription governor admits two terminals on one subscription and
12         refuses the third.
13  And the single live smoke: attempted through the real path -> skip-with-record (no live call), the
14  honest non-interactive outcome (directive $10.4) – the operator R8 $6 live-terms are unmet here.
15  """

1  """Phase 15C `.detect` (integration): the REAL Codex CLI presence/version/auth probe.
2
3  The honest LIVE proof for `.detect`. It actually spawns the benign, local, credential-free
4  metadata calls – `codex --version`, `codex login status`, `codex exec --help` – and asserts the
5  detection facts the `.adapter` supervised spawn gate will act on. It makes NO live model call
6  (`codex exec <prompt>` is never run). When `codex` is absent it SKIPS-WITH-RECORD (directive
7  $10.4, the exact operator remediation is printed) – never faked.
8
9  Entry condition (OP-7 item 1 / OP-8): `codex` installed + authenticated by the operator
10 (`npm install -g @openai/codex` ; `codex login`). If present but unauthenticated, the probe
11 still runs and records `authenticated=False` (a real, honest negative), OpenAI legs OWED.

1 | """Phase 15D `.selection`: the operator's conductor SELECTION (fable-5, OP-6) is carried through the
2 | REAL governed live-conductor spawn path, surfaced on EVERY outcome, and never conflated with the
3 | executing checkpoint (directive §11 15D).
4 |
5 | Proven here, through the real entrypoint + a REAL MCP server (mock backend only – no live call):
6 | 1. The governed spawn requests the SELECTION's model by default (fable-5), not the CLI default.
7 | 2. `conductor_selection` is surfaced on every smoke outcome – success AND skip-with-record – so
8 |    which conductor was selected is never silent, exactly like `model_resolution` (§11 15B).
9 | 3. The published CANDIDATE decision records the SELECTION and the executing model separately.
10 | 4. An executing checkpoint differing from the selection LABEL is surfaced as a label mismatch
11 |    (no label->checkpoint mapping exists yet); the selection is not rewritten.
12 | 5. Succession + restore round-trips the record through the REAL SuccessionManager: the successor
13 |    is `reason: succession`, and restoring returns the pinned operator selection with a new `since`.

1 | """Phase 17B `legs` – a LIVE WORKER publishes CANDIDATE over MCP through the governed loop, and
2 | its leg is DERIVED from its own evidence rather than asserted (directive §16 track 17B; closes the
3 | worker half of U58).
4 |
5 | Two things are under test and they are separable:
6 |
7 | 1. **The wiring** – an injected `WorkerHandle` is registered in the capability registry, resolved
8 |   BY DESCRIPTOR by the real Scheduler, executes the assignment, publishes a CANDIDATE over the
9 |   real MCP server, and is gated by the real gate engine into the conductor's synthesis.
10 | 2. **The leg honesty** – `derive_worker_legs` / `_assert_legs_honest` make a `live` worker leg
11 |   UNREPRESENTABLE without that node's own verification record, refuse a declared leg that
12 |   contradicts the evidence in EITHER direction, and refuse contradictory evidence outright.
13 |
14 | MOCK-FIRST (§10.4): every test here binds a deterministic backend or a fake verifier. No `claude`
15 | process is spawned by this suite – the live run is the operator-gated emitter, whose receipt is the
16 | evidence. A mock can never be recorded live, and that is itself asserted below.

1 | """U60 – a caller's loopback channel survives a long LIVE call, without ever re-applying a write.
2 |
3 | ROOT CAUSE (found at Phase 17B `legs`, 2026-07-26): U60 recorded the multi-minute live symptom as
4 | "transient loopback flakiness". It is not transient. `MCP`'s handler carries `timeout = 60`
5 | (an F6 resource guard: idle handler threads must not linger). A live `claude` worker call takes
6 | longer than that, so while the model runs the SERVER closes the caller's connection; the caller's
7 | next request then fails on the WRITE with `WinError 10053` and the governed run degrades – exactly
8 | what the first `legs` live attempt did.
9 |
10 | THE RULE UNDER TEST: a request whose WRITE failed never reached the server (it reads newline-
11 | delimited requests, and a partial write is not a request), so re-establishing and sending it again
12 | cannot double-apply it. A request whose write SUCCEEDED may already have been applied, so a lost
13 | RESPONSE is never retried – it fails closed (F5). These two halves are what make the reconnect safe
14 | rather than merely convenient, and both are asserted here.

1 | """Phase 15E `.objective` – the operator command surface end to end over a REAL MCP server.
2 |
3 | Proves the governed pause OP-7 §12.5 item 5 requires: the operator submits an objective, the
4 | conductor decomposes and the plan gate runs, the plan SURFACES in the approval drawer, and ONLY on
5 | operator approval does the LiveGovernedFlow assign → workers publish CANDIDATE → gates → the
6 | conductor synthesizes an acceptance packet. The two load-bearing governance properties:
7 |
8 | * invariant 1 – no worker is assigned until the operator approves (the plan pauses);
9 | * invariant 16 – a gate-failed plan is surfaced but cannot be approved into execution.
10 |
11 | MOCK-FIRST (§10.4): the conductor/worker legs are mock (`LiveGovernedFlow` default); no `claude`
12 | process is spawned. This proves the SURFACE and the governance around the flow, not a live model.

1  """Phase 14C `gate` (deterministic): the full governed chain from a driven worktree to the trunk.
2
3      driven worktree edit → node-local gate → CANDIDATE published to MCP → controlled merge
4
5  These tests use a REAL MCP server, a REAL git worktree, and the REAL `MergeCoordinator` – but a
6  DETERMINISTIC SEEDED worktree edit stands in for the model's output (directive $6, U31: a small local
7  coder did not complete a live schema-correct edit this session, so the governed path – the system
8  under test – is exercised with a scripted edit, and `from_live_model=False` records that). No
9  `opencode` is spawned here; the live spawn is proven in `.harness`/`.worktree`.
10
11  What is proven, all fail-closed:
12  - worker publishes CANDIDATE, never self-canonizes (invariant 10) + full provenance (invariant 11);
13  - a failed artifact cannot advance – a FAIL node-local gate is neither published nor merged (16);
14  - the trunk merge requires the passing gate AND operator approval (invariant 1);
15  - a different node promotes CANDIDATE→ACCEPTED; the author cannot (invariant 18).

1 | """Phase 14C `.gate` (live): drive REAL OpenCode, then run the governed CANDIDATE→merge chain.
2 |
3 | This is the honest live tie-off of Phase 14C: it spawns REAL `opencode run` (local, credential-free)
4 | through the supervised gate against the host's local Ollama coder, in a REAL isolated worktree, from
5 | a REAL scoped MCP entry – then packages the result as a CANDIDATE, gates it, publishes it to a REAL
6 | MCP server, and drives the REAL `MergeCoordinator` into the trunk. SKIPS-WITH-RECORD (directive
7 | $I0.4) when OpenCode or a local coder model is absent – never faked.
8 |
9 | HONESTY (directive $6, U31). A small local coder is flaky at COMPLETING a schema-correct headless
10 | edit. So the merge is driven by whatever the worktree holds AFTER the drive: if the live model landed
11 | a gate-clean edit, THAT is packaged (`from_live_model=True`); otherwise a DETERMINISTIC seeded edit is
12 | applied and `from_live_model=False` is recorded – the governed path (package → node-local gate →
13 | CANDIDATE publish → controlled merge) is the system under test and is proven either way. The test
14 | never claims a live landed edit that the model did not produce; the actual origin is printed and
15 | asserted from `from_live_model`.

1  """Phase 14C `.worktree` (integration): drive REAL OpenCode against a REAL local coder model, in a
2  REAL git worktree, from a REAL scoped MCP entry – the honest live proof of the middle 14C cell
3  (scoped MCP context → isolated worktree modification → tests run).
4
5  This actually spawns `opencode run` (local, credential-free – permitted outright, unlike a frontier
6  live call) and drives the host's local Ollama coder. It SKIPS-WITH-RECORD (directive §10.4) when
7  OpenCode or a local coder model is absent – never faked.
8
9  HONESTY (directive §6; recorded in the evidence report). What is RELIABLY proven and asserted:
10 - OpenCode itself is genuinely DRIVEN headlessly: it spawns, is pinned to the LOCAL Ollama model
11   (the run banner names it), runs its agent loop, and returns – through the supervised spawn gate
12   and the scoped session config (U30);
13 - the drive stays CONFINED to the node's worktree (no out-of-worktree modification: escaped=False).
14 What is RECORDED but NOT hard-asserted (a small local coder is flaky at COMPLETING a multi-step
15 tool edit headlessly – a model-quality limit, not a harness/governance defect): whether a file edit
16 actually landed (`edit_completed`) and how many tool signals appeared. When an edit DOES land, the
17 worktree's tests are run against it. The test never fabricates an edit the model did not produce.

1 | """U330's falsification, and the one the directive says is absent everywhere in this repo: a
2 | GENUINELY concurrent test – two OS processes, not two threads – publishing candidates and
3 | posting debate turns against the same task, proving neither is lost.
4 |
5 | Why two processes and not two threads. Every orchestration writer runs in its own MCP adapter
6 | process, one per live node. `persistence/store.py` holds a `threading.Lock` around its writes,
7 | so a threaded test is ordered by that lock and passes against code with no database transaction
8 | at all – it cannot see the defect. Only separate interpreters, contending through SQLite's own
9 | `BEGIN IMMEDIATE`, exercise what the product does.
10 |
11 | What "neither is lost" means concretely – with each claim labelled by what it can actually
12 | catch, because the round-1 gate-validator found one of them decorative (MAJOR-1) and the honest
13 | labelling is now part of the test:
14 |
15 | * **[falsifies]** every turn both processes believe they posted is IN the durable debate
16 | record, and each debate holds exactly `2 x rounds` of them. Measured: on the parent commit
17 | this assertion failed on every run;
18 | * **[falsifies]** no node's candidate revision on the task record ever goes BACKWARDS, watched
19 | by a third process (`operational_race_watcher.py`) sampling the record while both workers
20 | write it. A revision is monotone by construction, so one regression IS a lost update.
21 | Getting this claim to a state where it could fail took four drafts, each measured against the
22 | defect spliced back into `record_candidate` rather than reasoned about:
23 |     1. publish once at the end → 0/3 detection (the turn loops drift the processes apart, so no
24 |        candidate write ever contends). This is the decorative version the round-1 validator
25 |        caught;
26 |     2. publish once per round, assert the FINAL revision → 1/3 (the final state only reveals a
27 |        loss in the last write);
28 |     3. publish after every turn and have each WRITER watch its peer → 2/5. A writer cannot see
29 |        the damage it does: it destroys the PEER's revision, and its own pre-transaction snapshot
30 |        is never older than what it last read, so its view of the peer is monotone either way;
31 |     4. a third process watching, plus a 1000-revision burst per worker where both hammer the
32 |        one task row back to back → **6/6 detection, 0/4 false positives on the fixed tree**.
33 | The burst is why the detection is reliable: interleaved with debate turns the vulnerable
34 | read-to-commit window is a fraction of each writer's loop, and a fifth of runs found it;
35 | * **[falsifies, but never first]** the per-node round set `1..ROUNDS`. The CEILING cannot be
36 | breached across processes however the successor is built – each node is the sole writer of its
37 | own turns – so this claim does not grade the bounded-round rule (the racing unit test in
38 | `tests/unit/test_operational_write_path.py` §2 and mutation row F2 do). It does fail under a
39 | lost-turn schedule, because a node whose turn was destroyed recomputes a duplicate round
40 | number; assertion 1 simply reaches that failure first;
41 | * **[falsifies]** every turn produced its peer message – the append-only path, verified
42 | alongside so a regression that trades one loss for another is visible;
43 | * the store's own integrity check still passes.
44 |
45 | The test is deliberately mute about ORDER. Two concurrent nodes have no canonical interleaving,
46 | and asserting one would be asserting a scheduler. What it asserts is that nothing was dropped.
47 |
48 | One correction to the directive's premise, since repeating it would be the easy error: a
49 | two-process falsification is not absent from this repo – `tests/integration/test_mcp_cross_process_race.py`
50 | has raced the CAS fence since Phase 3A. What was absent is one for the OPERATIONAL collaboration
51 | writers, which is why five of them could bypass their transaction for two phases unnoticed.

1  """Real-microphone capture path – Phase 17C `.mic` (directive §16 track 17C).
2
3  Everything up to `.mic` was driven by a scripted `audio:` ref that carries no PCM, so the real engine
4  was structurally unreachable from the shell. These tests pin the two seams `.mic` adds, WITHOUT a
5  microphone and WITHOUT a live NeMo (an injected runner stands in for `wsl.exe`), so they are
6  deterministic on any host:
7
8  1. **`seed_probe_result`** – the cross-process probe answer (**U134**). The emitter is a one-shot
9  process whose probe cache is always empty; a real capture that had to re-probe would either pay
10  7–22 s on top of the transcription the operator is already waiting for, or (non-blocking) see
11  `unprobed`, decline the real engine, and route the operator's actual speech to the MOCK. That is
12  U74 re-staged at the process boundary. The load-bearing property is that a seed can only ever
13  SKIP a redundant import – it can never fabricate a transcript.
14  2. **the emitter's `--real-capture` argument surface** – that a real WAV selects the real engine
15  (`for_capture=True`, blocking), that a stand-in never does, and that only a POSITIVE engine state
16  is honoured (a negative must not be able to suppress the real engine across the seam).
17
18  The live end-to-end transcription is proven on this host by the in-Electron `.mic` receipt and by
19  `tools/live/real_parakeet_smoke.py`.

1  """No pytest run may spend a live provider-subscription call (U163).
2
3  The mock-first suites already tried to guarantee this, each in its own way – `patch.object(
4  claude_code_module.subprocess, "run", ...)`; `monkeypatch.setattr(subprocess, "run", forbidden)`.
5  Those patches stopped intercepting on 2026-07-28, when the frontier adapter moved its spawn from
6  `subprocess.run` to `run_managed_process` (commit c8af621, the descendant-killing job boundary).
7  Nothing failed: the calls simply became REAL. Measured on 2026-07-30, `pytest tests/` spent live
8  `claude` calls in three `test_live_debate_flow` cases and reported a `live` leg for a suite whose
9  own docstring says `live` must be unreachable in it – the checkpoint was genuine, which is
10 precisely the problem.
11
12 So the seam is no longer allowed to be per-test knowledge. This guard sits at the process boundary
13 itself and refuses, by executable NAME and argument vector, any BILLABLE spawn of a provider CLI
14 from inside the test suite:
15
16 * it patches the definition site, so modules imported later bind the guarded function;
17 * it patches every already-imported module that holds a `from ... import run_managed_process` name;
18 * it covers `subprocess.run` / `Popen` too, since a future adapter could route either way.
19
20 It does NOT restrict ordinary spawns (node, python, powershell, wsl) – those are how several tests
21 prove real behaviour. Live provider work belongs to the `tools/live/` smokes and the in-Electron
22 self-checks, which run outside pytest and record receipts. A test that genuinely must reach a
23 provider can mark itself `@pytest.mark.live_cli`, and that mark is then visible in the diff.
24
25 Nor does it restrict the CREDENTIAL-FREE METADATA calls (U165). Refusing by executable name alone
26 also refused `codex --version`, `codex login status` and `codex exec --help` – the local probes
27 Phase 15C `.detect` is built on, which reach no model and cost nothing – and turned nine honest
28 host-probe tests red the moment the guard landed. The line the guard actually defends is
29 `*spending a subscription call`, so the allowance is drawn there and drawn TIGHT: the WHOLE argv
30 must equal one of the enumerated forms below. `exec --help` is free; `exec --help <prompt>` is a
31 model call wearing its clothes, and a bare `codex` opens the interactive session – both refused.
32
33 This lives in its own module, not in `conftest.py`, so that a test can import the exception class
34 and get the SAME object the fixture raises (pytest loads a rootdir conftest under its own module
35 name, and an importing test would otherwise catch a different class of the same name).
36 """

1  """Phase 17A `roundtrip` – the live model-availability PROBE (tests first).
2
3  The operator's conductor selection is a LABEL ("fable-5"). Whether the host `claude` CLI accepts
4  that label as a `--model` slug is not knowable offline, and the shell was launching with it
5  unchecked: the live session started, painted its banner, took the keystrokes – and answered every
6  prompt with "There's an issue with the selected model (fable-5)". A live session that cannot answer
7  is the black pane with extra steps.
8
9  These tests pin the probe's rules with ZERO live calls (injected fake backends):
10 * a slug is ACCEPTED only when a real one-shot call ran on it – never by assumption;
11 * an error text that says the model is unavailable moves to the NEXT candidate;
12 * a "successful" reply whose TEXT is the CLI's own model-unavailable message is NOT acceptance
13   (the CLI reports that condition inside a 0-exit response, so exit status alone is not evidence);
14 * an auth/rate condition proves NOTHING about the slug   inconclusive, and the record is not
15   allowed to demote the operator's selection;
16 * exhausting the candidates with model-unavailable answers is the CLI-DEFAULT FALLBACK, recorded
17   and surfaced (directive §11 15B / §16 17A: "unavailable   recorded fallback, never silent").

1 | """U53 discharge – a closed conductor cannot act (`phase-15d.gate`).
2 |
3 | `phase-15d.succession`'s central claim is that the predecessor is GONE. The gate-validator found
4 | that claim rested on the runner's discipline rather than on construction: `run_cycle` refused once
5 | closed, but the two other MCP-touching methods beside it – `read_accepted` and
6 | `publish_acceptance_packet` – did not. A corpse could still read project state and publish an
7 | acceptance packet over MCP.
8 |
9 | These tests pin the refusal at the adapter, which is where the fix belongs: every caller of a
10 | closed conductor now fails closed, not just the callers that remembered to check.
11 |
12 | RESIDUAL, not closed here and recorded in the register: `McpClient.call` auto-reconnects, so a
13 | closed conductor's *client* can still re-establish a session. The refusal above is the adapter
14 | declining to act; it is not the transport making action impossible.

1  """Phase 15C `.detect` (unit): the Codex CLI detection/probe surface.
2
3  Deterministic, no-subprocess proofs of the probe logic for every branch (present/authed,
4  unparseable version, below-minimum, unauthenticated, absent). The load-bearing properties:
5  - the probe NEVER raises – every failure is captured as fail-closed data (Buildout $4);
6  - unparseable / below-min version  meets_minimum False (fail closed, never passes);
7  - a non-positive/ambiguous `login status`  authenticated False (never assume auth on silence);
8  - the operator-named GPT-5.5 models are recorded UNVERIFIED (no offline enumeration; the
9    accepted id is a live-smoke fact for `.adapter`) – never fabricated as a confirmed CLI slug.
10 The real `CodexCli` (which would spawn `codex`) is NEVER invoked here; the live probe is in the
11 integration suite. `codex exec` is never called anywhere in `.detect` (no live model call).

1 | """U326 – the collaboration path must ask `control_plane/policy.py`, and only it.
2 |
3 | Invariant 7: *MCP is access, not authority – no authorization logic inside `mcp_server/`.
4 | `mcp_server/memory_service.py` has always honoured that; `mcp_server/collaboration_service.py`
5 | took a `SovereignPolicy` in its constructor, never read it, and made FIFTEEN role/permission
6 | decisions inline instead (cold audit finding B1, 2026-08-06, which named twelve of them).
7 |
8 | Four kinds of test live here, and all four are needed. A rule test alone cannot tell a
9 | delegated rule from a duplicated one – the assertions pass either way. So:
10 |
11 | * **the rule tests** (§3) go through `CollaborationService` and pin each decision's behaviour.
12 |   They are the mutation targets: a mutation to a rule in `control_plane/policy.py` must turn
13 |   one of them RED, which is what proves the delegation is LIVE rather than decorative;
14 | * **the injected-policy tests** (§2) require the service to follow a policy that disagrees
15 |   with the shipped one – in the PERMISSIVE direction, which is the only assertion a second
16 |   copy of a rule inside `mcp_server/` cannot survive. There is one per entry point, because
17 |   the first version of this file had one in total and the reviewer's answer to "could these
18 |   tests pass against a duplicated rule set?" was "yes, for eleven of the twelve";
19 | * **the direct-policy tests** (§5) cover the clauses that are DEFENCE IN DEPTH – unreachable
20 |   from the collaboration path because the store scopes its reads by project before the policy
21 |   is asked. Labelling them honestly matters: a mutation row graded by one of these has not
22 |   been proven through the collaboration path, and the harness says so at the row;
23 | * **the verdict matrix** (§7, U352) pins the WHOLE surface – every admitted role x every
24 |   operation – as one table, because four consecutive review rounds each found a different
25 |   membership set or scope clause that the one-off rule tests did not pin, always in the
26 |   widening direction. A table cannot be widened one constant at a time without a cell moving.

1113 |
1114 |
1115 | class TestTheWholeVerdictSurfaceIsPinned:
1116 |     """Four consecutive review rounds found the SAME defect: a deny statement was pinned by a
1117 |     test while the membership set or scope clause behind it was not, so widening it left the whole
1118 |     suite green – ` _SCOPED_ROLES` (round 1), ` _DIRECTING_ROLES` toward `gate` (round 2), four more
1119 |     constants (round 3), and then ` _DIRECTING_ROLES` toward `voice`, the debate closer's identity
1120 |     and `authorize_open_debate`'s subset (round 4). One-off tests cannot end that: each round pins
1121 |     the widening the round before it found, and the next reviewer finds the next one.
1122 |
1123 |     This table is the structural answer. Every role the policy admits, driven through every
1124 |     collaboration operation on a deterministic world, with the exact outcome recorded. No change to
1125 |     ` _SCOPED_ROLES` or ` _DIRECTING_ROLES` can pass it: such a change moves a cell, and a moved cell
1126 |     is a failure until someone regenerates this table on purpose and says why. (` _ROLES` is pinned
1127 |     instead by `test_the_table_covers_every_role_the_policy_admits` and by
1128 |     `test_every_role_the_policy_admits_has_a_pinned_collaboration_reach` – adding a member moves no
1129 |     cell here unless the added name is one an identity already carries, and only `hacker` is.) It
1130 |     goes through
1131 |     `CollaborationService`; no policy method is called by the grader. Recorded as U352.
1132 |
1133 |     What it does NOT catch, demonstrated at round 5 rather than assumed (U353) – the table pins ONE
1134 |     deterministic world, so a rule is invisible to it when the world never puts that rule's input in
1135 |     front of a policy call: a clause keyed on a task status (`COMPLETED`) this world never reaches,
1136 |     on a debate state (`CLOSED`) no policy call here is ever asked about, or on a message kind
1137 |     (`decision`) never written; an extra name admitted by `_unknown`; a role dimension this world
1138 |     holds at one value – `authorize_debate_turn` has no role clause at all and its participants here
1139 |     are workers only, so adding one would be unobserved (U355); and a clause an earlier gate answers
1140 |     first, so it is never asked – `authorize_send_message`'s sender clause (U343).
1141 |     Four such widenings were shown green against the whole suite at round 5 (2,331 passed, 1 skipped).
1142 |     Widen the world before trusting the table with a new rule shape."""

1  """Governed conductor-first pane spawn (Phase 15E `.conductor-pane`, directive §13 / OP-8).
2
3  `pane_node_spawn` refuses the conductor role and points here. These unit tests prove, WITHOUT a
4  live call, that the dedicated conductor path:
5
6  * opens the conductor pane through the SAME fail-closed frontier live gates the worker path uses
7    (LIVE_OPERATION_AUTHORIZED, provider-live, R8 §6 operator terms, CLI presence, I-X3), and TEARS
8    DOWN releasing the governed count (D-LOOP-1);
9  * builds an INTERACTIVE `claude` launch (no `-p`, no `--output-format json`) – the operator drives
10 it – with a credential-scrubbed env (§2.2);
11 * produces the CONDUCTOR chrome: pinned pane 1, `attended` mode, model badge = the SELECTION label
12 (fable-5), executing checkpoint UNVERIFIED until a live reply (invariant 3);
13 * surfaces the Resume>Select succession affordance reachable from chrome;
14 * refuses fail-closed on a naked identity, a missing subscription (uncounted terminal), an
15 unauthorized live_auth, unconfirmed operator terms, and an absent CLI.

1 | """Phase 15D `.selection`: the conductor SELECTION record is deterministic, schema-pinned, and
2 | never conflated with the EXECUTING checkpoint (directive §11 15D: ``current_conductor` =
3 | {model: fable-5, reason: operator_selected, since: 2026-07-19} – selection preserved even when the
4 | executing checkpoint differs, record BOTH").
5 |
6 | Load-bearing properties proven here:
7 | 1. The pinned operator selection IS fable-5 / operator_selected / 2026-07-19 and validates against
8 | the FROZEN checkpoint@1.0 `current_conductor` definition (schema is the source of truth).
9 | 2. Selection is an INTERFACE label (invariant 3): binding it to a live backend never rewrites it,
10 | and an executing checkpoint that differs from the selection LABEL is surfaced as a
11 | label/checkpoint pair (not adjudicated as a divergent model), not masked.
12 | 3. Fail closed: blank model, unknown reason, non-ISO `since`, unknown record keys all RAISE –
13 | never coerced into a permissive default.
14 | 4. An unverified/unavailable model becomes a RECORDED fallback (never silent), and a checkpoint id
15 | is never fabricated (`executing_verified` is True only when a live reply reported one).
16 | 5. Succession changes only the selection (reason=succession); restoring returns the pinned
17 | operator selection with a NEW `since` – the clock is injected, never read here.

1 | """The voice-turn hook must be RUNNABLE by the vendor CLI's own hook dispatcher (U162).
2 |
3 | Iteration 92's exact-source live receipt (PHASE17C_CLOSE_SELFHECK, 2026-07-30) reached the live
4 | conductor and then failed four containment legs with the pane showing::
5 |
6 |     UserPromptSubmit hook error
7 |     Failed with non-blocking status code: At line:1 char:36
8 |
9 | `char:36` is exactly one past ``"<node.exe>" `` - PowerShell's parser, refusing a command line whose
10 | FIRST token is a quoted string (it reads it as an expression, and the second string is then an
11 | unexpected token). The pinned `hook_command` was `subprocess.list2cmdline([node, hook])`, which is
12 | correct CreateProcess quoting and INVALID PowerShell. So no hook ran: no turn was armed, the model's
13 | tool call was never denied by the supervisor, and the vendor's own approval prompt caught it instead.
14 |
15 | The lesson is not "quote differently" - it is that a hook whose command string the dispatcher cannot
16 | parse FAILS OPEN for tool denial while every unit test that checks the string still passes. These
17 | tests therefore execute the emitted command through the real dispatcher, and require the profile to
18 | refuse to build when that execution cannot be proved.

1 | """Phase 16C `dispatch` – the governed CONDUCTOR dispatch feed the shell sources on launch.
2 |
3 | Proves the emitter drives the REAL governed dispatch (`control_plane.orchestration.live_flow`) through
4 | its full loop (decompose → assign BY DESCRIPTOR → CANDIDATE over MCP → real gate engine → conductor
5 | synthesis) and folds it into the stable `conductor_dispatch_feed@1.0` shell contract – MOCK-first, no
6 | live model call – closing U58 exactly as far as the non-interactive evidence allows:
7 |
8 | * governed happy path `dispatched:true`, routing BY DESCRIPTOR (invariant 4), ≥1 gate-ACCEPTED
9 | artifact (invariant 18 – the GATE node's PASS, not the synthesizer's), HONEST mock-first legs
10 | (`conductor=mock`, `workers=mock` – never a claimed live worker leg), the packet's
11 | `operator_disposition` "pending" (gate promotion is NOT operator acceptance, invariant 1), the LIVE
12 | worker leg recorded OWED (U58), and D-LOOP-1 proven (`torn_down:true`);
13 | * the pure fold (`fold_dispatch_feed`) is deterministic and invents nothing; a plan-blocked trace
14 | folds to a fail-closed `dispatched:false` with the plan verdict as the reason;
15 | * a fault (`build_conductor_dispatch_feed` over a broken store) the un-dispatched feed, never a
16 | fabricated dispatch (invariant 3);
17 | * `--emit-conductor-dispatch` prints ONLY the feed JSON and exits 0; any other invocation is a
18 | fail-closed usage error (exit 2).

227 |
228 |     17E `.close` measured this: a live `claude` worker answered the bare smoke objective in prose
229 |     containing an informal incompleteness marker, the real STAGE gate refused the artifact on
230 |     `no_placeholders` (a CRITICAL criterion), and the assembled leg went red on a live answer that
231 |     was otherwise perfectly good work. The node was judged by a rule nobody gave it. Telling it the
232 |     criteria is scoped need-to-know (Plan §9), NOT a softened gate: the gate still computes its
233 |     verdict from the published bytes and still refuses an artifact that trips one.
234 |
235 |     The trap this test exists for: the objective travels INTO the artifact body
236 |     (`ModelWorkerAdapter.execute`), so a brief that spelled out the marker words would make
237 |     `no_placeholders` fail on EVERY run, for the text of the instruction itself.
238 |
239 |     Two corrections from the 17E `.close` spec-audit are pinned below. (M3) The refusal run the
240 |     docs cite as evidence that this gate refuses live work was produced under the BARE objective –
241 |     it is evidence about the gate FUNCTION, not about the briefed path. (m1) The brief must not tell
242 |     the node it is judged on `claims_cite_evidence`: that criterion reads the ADAPTER's generated
243 |     claim records, which the node's prose cannot affect. Only `no_placeholders` binds its wording.

1 | """Governed CONDUCTOR LAUNCH TICKET emitter (Phase 17A `.lease`).
2 |
3 | `emit_conductor_spawn` proved pane 1 goes through the full live-gate chain, but it deliberately
4 | DEFERRED the interactive `claude` drive and tore its I-X3 terminal down before emitting – so the
5 | shell had gates without a session, and a count that died with the emitter. 17A needs the opposite
6 | shape: a ticket the SHELL can execute, whose terminal stays counted for as long as the shell holds
7 | the session.
8 |
9 | These tests pin that contract without a live call:
10 |
11 | * the ticket is produced ONLY through the same gate chain (`spawn_conductor_pane`): live-operation
12 |   authorization, provider-live, R8 $6 operator terms, `claude` presence, I-X3;
13 | * the ticket carries an INTERACTIVE argv (no `-p` / `--output-format json`) and the NAMES (never
14 |   the values, §2.2) of the credential-bearing env vars the shell must drop before spawning;
15 | * the durable lease is HELD when the ticket is emitted (`in_use == 1`) – unlike the 16C spawn feed,
16 |   the count deliberately survives the emitter, because the session will;
17 | * the in-process governor is still released (D-LOOP-1 for the emitter's own bookkeeping) – the
18 |   DURABLE lease is the only thing that outlives it, and it is explicitly named in the ticket;
19 | * a durable count already at the allowance REFUSES the ticket – the shell cannot launch an
20 |   uncounted third terminal even though its own governor is empty;
21 | * every governance refusal (unauthorized live config, unconfirmed terms, absent CLI, corrupt
22 |   ledger) yields a fail-closed REFUSAL ticket with a reason and NO argv – never a fabricated
23 |   authorization, and never a leaked lease;
24 | * release is a first-class emitter mode, so the shell can hand the terminal back when the session
25 |   ends (and the loop can prove no lease outlived the work unit).

1  """The 18D ``close`` node-registration REPORT – the producer behind the in-Electron receipt.
2
3  Why this file exists at all: at the 18D ``amendment`` gate the validator found that the shipped OWED
4  block had no red-able test – every rule ran only at in-Electron emit time and every test asserted
5  against a synthetic fixture, so replacing a claim with a stronger one left all three suites green
6  (U296). These tests drive the REAL ``build_report()`` and then break each of its ``ok`` conjuncts in
7  turn, so every claim the receipt makes has a way to go red in the ordinary suite.
8
9  The report reads the operator's real switch (read-only) and runs the real governed session under a
10 fixture switch in a scratch directory. It executes no CLI and makes no live call, which is why it is
11 safe in a deterministic suite – and ``test_no_child_is_ever_spawned`` is the assertion, not the
12 comment.

1  """Phase 16D `.statusbar` – tests for the governed subscription-status feed emitter.
2
3  Proves the emitter (`tools/live/emit_subscription_status.py`) builds a REAL `SubscriptionGovernor`
4  seeded from the enforced `LiveAuthorization` scope and emits a readable n/allowance count – the count
5  the shell status bar renders instead of "currency count unavailable" – and that it is:
6  * SCHEMA-pinned (a drifted producer is refused by the shell source);
7  * HONEST (in_use = 0 with no held terminal; the count is the authorized ceiling; live per-session
8    tracking recorded OWED to 16F – never fabricated);
9  * FAIL-CLOSED (a DENIED / malformed authorization status:null, the em-dash unknown, not 0/2);
10 * a pure record – no model call, no credential ($2.2/$2.4).

1 | """Governed WORKER LAUNCH TICKET emitter (Phase 17B `.ticket`; directive §16 track 17B, U70).
2 |
3 | The conductor got its executable authorization at 17A `.lease`; a picker selection still got nothing
4 | – it was recorded and badged, and the pane stayed empty (operator finding F3). This emitter is the
5 | worker's equivalent: ONE picker selection in, a governed ticket the shell can execute out, or a
6 | fail-closed refusal.
7 |
8 | These tests pin that contract without a live call:
9 |
10 | * the ticket is produced ONLY through the governed chain (`authorize_worker_pane`), and a FRONTIER
11 |   ticket carries a DURABLE I-X3 lease that is still held when it is emitted (the session outlives
12 |   the emitter) while the emitter's own in-process count is released (D-LOOP-1);
13 | * a LOCAL ticket carries NO lease and says so (`subscription_governed:false`) – invariant 19: a
14 |   local model is governed by VRAM residency, not by a subscription – and carries its residency;
15 | * a durable count already at the allowance REFUSES a frontier ticket, even though the emitter's own
16 |   governor is empty (the cross-process half of I-X3);
17 | * every refusal (greyed option, conductor role, unauthorized live config, absent CLI, unfittable
18 |   model, malformed selection) is a well-formed REFUSAL ticket with a reason and NO argv and NO
19 |   lease – never a fabricated authorization, never a leaked terminal;
20 | * the CLI reads the selection from STDIN and prints exactly one JSON line; a usage error exits 2
21 |   with no JSON (the shell treats that as "unavailable", never as a launch).

```

1 | """The HOST VRAM budget rule - `tools/live/enumerate_pane_picker._host_residency`.
2 |
3 | 17B promoted this function from a 16B display chip into an AUTHORIZATION gate (a local worker pane is
4 | admitted or refused on the free VRAM it computes) and it shipped with no regression coverage at all.
5 | Three gate-validator passes were spent on the arithmetic; this suite is what stops the fourth.
6 |
7 | The defect class under test (gate-validator B1 → BLOCKING-1, 2026-07-26): the budget was DERIVED from
8 | the resident set - first `total = sum(running)`, then `total = max(running, floor)`. Either way the
9 | same models define the budget and then consume it, so free VRAM collapses to 0 whenever the running
10 | total reaches the budget, and every local pane is refused for a reason that is an artifact of the
11 | heuristic rather than a fact about the host. The rule now fixes the budget BEFORE reading residency,
12 | and when the host's own residency contradicts it, says so instead of manufacturing capacity.
13 |
14 | The daemon is injected (`_daemon_json`), never contacted: these are arithmetic facts, and a test that
15 | depended on what the operator's Ollama happens to be serving would be the same non-determinism the
16 | validator caught in the receipt.

1 | """U45 discharge – the ONE checkpoint-verification rule, applied at every site (`phase-15d.gate`).
2 |
3 | `.debate` established the rule that backs a `live` claim (exact vendor type + a non-blank checkpoint
4 | the CLI itself reported + freshness against a bind-time snapshot + evidence a call was spent) but
5 | applied it in ONE module. U45 recorded that three already-gated sites kept the pre-fix behaviour:
6 |
7 | 1. `live_flow._leg_for_backend` – subclass-permissive `isinstance`
8 | 2. `selection.bind_conductor_selection` – verified from a caller-supplied string, no type, no freshness
9 | 3. `claude_code.ClaudeCodeConductorBackend.propose_plan` – no freshness
10 |
11 | These tests pin the discharge. They are written against the DIRECTION that matters: every route by
12 | which a run that did NOT reach a real provider could be recorded as one must be refused. The
13 | positive `live` contract is exercised only at the classifier level with fabricated instrumentation,
14 | never end to end – reaching `live` for real requires spawning a `claude` process, which this
15 | MOCK-FIRST suite must not do (the posture `.flow`/`.debate` adopted).

1  """Phase 15D `.succession` – the pure honesty/comparison layer.
2
3  Directive §11 15D: "kill the Fable-5 conductor mid-run, resume on a different backend, zero loss,
4  then restore selection." These tests pin the parts that decide whether that claim may be MADE:
5
6  - a zero-loss verdict that cannot be reached vacuously (an empty pre-kill set proves nothing);
7  - a `different backend` claim that must be structurally provable, not asserted;
8  - leg vocabulary reused from `live_flow`/`live_debate`, with `live` unbacked by a verification
9    record being UNREPRESENTABLE rather than merely discouraged;
10 - I-X3 handoff ordering (release BEFORE acquire) recorded from observation, never assumed.
11
12 No MCP server, no adapters, no clock – every input is injected.

1  """What the operator is SHOWN must agree with what the admission gate will DO.
2
3  spec-audit MAJOR-2 (2026-07-26), against the 17B `.ticket` fix commit: `pane_picker._local_options`
4  hard-coded `available: True` for every enumerated Ollama model, with the recorded rationale "no
5  credential gate for a detected local model". That was correct at 16B, when residency was a display
6  chip. 17B promoted the residency planner into an AUTHORIZATION gate, and there are now host states –
7  a budget the host's own residency falsifies, a residency seeding fault – in which
8  `worker_pane_spawn._authorize_local` refuses EVERY local pane while the picker still renders all of
9  them as launchable. Fails closed at the authorization, so it was never exploitable; it is the
10 "what the operator is shown is not what the gate enforced" divergence (invariant 27), and it is a
11 state the fix commit itself created.
12
13 Also covers the containment claim the enumeration makes about itself: "a residency fault must NEVER
14 escape this enumeration" was delivered by `except ResidencyError`, one exception class wide – a
15 daemon answering `/api/tags` with a JSON array took the whole picker down, frontier options
16 included, which is the BLOCKING-1b failure shape via `AttributeError` (spec-audit MINOR-5).
17
18 The daemon is injected, never contacted.

1 | """OP-12.1 / U227 – the node schema is amended by SUCCESSOR, and the freeze is not touched.
2 |
3 | Operator ruling OP-12.1 (`AUTONOMOUS_BUILD_DIRECTIVE.md` §17.1, 2026-08-01) resolves U227 by
4 | authorizing `schemas/node.schema@1.1.json` beside the frozen `@1.0` – enum = the frozen list plus
5 | `grok_build`, `google_antigravity`, and (as its own recorded item, U254) `ollama_local`.
6 |
7 | Four claims are load-bearing and each has a test here that fails when the claim stops being true:
8 |
9 | 1. **The freeze is untouched.** `node@1.0`'s file, `id`, enum and `schema` const are byte-for-byte
10 | what the Phase-0 manifest recorded, and the frozen schema SET is still exactly twelve files.
11 | 2. **The successor is a copy with exactly five recorded deltas.** Draft-07 cannot express
12 | "`node@1.0` with a wider enum" (`$ref`/`allof` can only narrow, and `additionalProperties:false`
13 | + the `schema` const would reject a `node@1.1` record), so `@1.1` is standalone – which means a
14 | duplicated document, which means drift risk. The delta test is the thing that manages it.
15 | 3. **The fence still fences.** `NodeRegistry.register` admits what a schema version admits and
16 | refuses everything else, auditably; the vocabulary is DERIVED from the files, not re-declared;
17 | and an unreadable schema narrows it rather than opening it.
18 | 4. **The manifest records the amendment without disturbing the signature.** `freeze_integrity_sha256`
19 | is unchanged and `operator_signature` survives regeneration (U222), while amendment drift is
20 | still a hard `--check` failure.

1  """phase-18c.close – pin the OP-12 acceptance verdict's JS constants to their Python authorities.
2
3  `apps/desktop/selfcheck/op12-acceptance-verdict.js` decides what the 18C in-Electron receipt is
4  allowed to CLAIM. Three of its constants are authoritatively owned in Python, and a stale JS mirror
5  would not fail loudly – it would produce a receipt that looks green while measuring the wrong thing:
6
7  * ``OP12_PROVIDERS``      ← ``adapters.frontier.grok_build`` / ``.antigravity`` adapter ids
8  * ``OP12_CREDENTIAL_NAMES`` ← ``adapters.frontier.provider_cli_common.PROVIDER_CREDENTIAL_ENV_KEYS``
9    (a SUBSET, deliberately: the receipt plants a sentinel under each name it lists, and it lists the
10   key-bearing ones. What may never happen is a name staying in the JS list after leaving the
11   authority – the receipt would then plant a sentinel under a variable nothing scrubs and report a
12   clean scan as evidence about a name the build no longer classifies.)
13  * ``OP12_ALLOWANCE``      ← ``live_authorization.provider_terminal_cap`` (operator directive
14   $12: allowance 1 each, never merged, never raised without a separate operator amendment)
15
16  The subscription REFS are not pinned here because they are not re-declared: the verdict module
17  imports ``ADAPTER_SUBSCRIPTION_REF`` from ``apps/desktop/picker/launch-source.js``, which
18  ``test_statusbar_constants_pinned`` already ties to ``canonical_subscription_ref``. Asserted rather
19  than assumed – the import is checked below, so a future edit that re-types the strings locally is
20  caught by this test rather than by a lease written to a bucket nothing reads (the U76 defect).

1 | """Phase 18B `.adapter` – deterministic tests for the two OP-12 frontier provider adapters.
2 |
3 | Covers the operator directive §16 items that belong to the ADAPTER sub-step: model enumeration,
4 | missing executable, version parsing, authentication classification, headless command construction,
5 | credential non-disclosure, and the argv/permission guard. Nothing here spawns a provider process
6 | or touches the network: every probe is driven through an injected fake runner, and the only
7 | backends the suite constructs are the mocks.
8 |
9 | Three owed items from the 18A gate are closed here and pinned so they cannot silently reopen:
10 | * **U249** – single-dash flag spellings (`-dangerously-skip-permissions`, `-mode accept-edits`)
11 |   walked through a guard whose docstring called it structural. Both sides are dash-normalised now.
12 | * **U250** – the endpoint-override and agent-identity flags the recorded capture documents were
13 |   in neither the forbidden list nor U235, while the module claimed no endpoint override could
14 |   redirect a call (true of the env surface only).
15 | * **U235** – instruction-injection flags stay OUT of the permission list (that decision is
16 |   preserved verbatim) and become a separately-named untrusted-input set the adapter never emits.

1 | """Phase 18B `.picker` – the two OP-12 providers in the per-pane picker and in the governed
2 | interactive pane authorization. Pure/deterministic: no CLI is spawned and no credential is read.
3 |
4 | What these tests hold to, stated once so a later edit has to argue with it:
5 | * a model id is NEVER invented – the option set IS the CLI's own `models` listing, and an
6 |   unenumerated provider yields zero options WITH a reason (operator directive §8/§14);
7 | * every refusal names the RIGHT provider – one provider's message under another's label is the
8 |   §14 defect this file mutation-checks;
9 | * the I-X3 buckets are separate and capped at 1 EACH, never merged (§12);
10 | * the interactive argv is a TUI launch (no `-p`, no `--output-format`) with the permission mode,
11 |   workspace and (grok) cross-session memory pinned (§9/§11, T2).

1 | """Phase 18C `.probe-path` – the GOVERNED, SUPERVISED session the OP-12 live probe runs inside
2 | (discharges U234).
3 |
4 | 18A built the probe and refused to run it: the child would have been a bare `subprocess.run` with
5 | no node identity, no I-X3 lease and no teardown accounting – a naked session (invariant 2 / I-C1).
6 | 18B `.scope` removed the impossibility that had kept that refusal academic (an OP-12 config can now
7 | open the live gate), so `_SUPERVISED_PROBE_PATH` = False` became the ONLY thing between
8 | `-Action probe` and an unsupervised frontier CLI. The 18A round-4 validator ruled that opening the
9 | switch before this path exists is *a gate failure at 18C*.
10 |
11 | This module pins the path itself, entirely offline – no CLI is resolved, no child is spawned, no
12 | live call is made. Every test drives `governed_probe_session`, a context manager that runs the SAME
13 | gate chain the interactive pane authorization runs (`_authorize_frontier`), in the same order, and
14 | then holds a DURABLE I-X3 lease for exactly as long as the one-shot child runs:
15 |
16 |     profile/live gate -> assert_provider_live -> R8 $6 operator terms -> CLI presence (per-provider
17 |     exception, operator directive $14) -> durable lease acquire -> [child] -> release on EVERY path.
18 |
19 | What is deliberately NOT claimed here: a Sovereign node RECORD. OP-12.1 (2026-08-01) ruled U227 by
20 | successor schema, so `NodeRegistry.register` now ADMITS both adapter ids under `node@1.1` – but
21 | nothing in this module was wired to call it, then or now. The session mints a governed IDENTITY (the
22 | same way `worker_identity` does for a pane, which also registers no record) and says so. The reason
23 | narrowed from "the vocabulary refuses it" to "no caller creates one"; the claim did not.

1 | """Phase 18B `.scope` – OP-12 live scope + per-provider subscription allowance (directive §17;
2 | operator directive §12/§13; register OP-12).
3 |
4 | What this pins, all deterministic and fail-closed (no network, no CLI, no live call):
5 |
6 | * **The scope is code-pinned per authorizing register row.** `OP-6` authorizes exactly the two
7 | providers it always did; `OP-12` authorizes those two PLUS `grok_build` and
8 | `google_antigravity`. A config citing OP-6 while naming a Grok/Antigravity provider RAISES –
9 | a config can never borrow another row's scope, which is the same property U237 found broken
10 | from the other end (the instruction "extend `config/live_operation.json`" was impossible
11 | because the code pinned the OP-6 pair and raised on anything else).
12 | * **Per-provider terminal allowance.** Operator directive §12: `grok_build_subscription` and
13 | `google_antigravity_subscription` are SEPARATE resources at allowance **1 each**, never
14 | merged, never raised without a separate operator amendment. The existing pair stays at the
15 | OP-6 allowance of 2. The cap is code-pinned, so an operator config that says
16 | `terminals_per_subscription: 2` still yields 1 for the two new providers.
17 | * **Three independent layers refuse a widened allowance** – `LiveAuthorization.terminals_for`,
18 | `SubscriptionGovernor.register_subscription`, and the durable `TerminalLeaseLedger.acquire`.
19 | * **No shorthand aliases for the new providers.** `codex` normalizes to `openai_codex_cli`
20 | because that alias is unambiguous. `gemini` is NOT an alias for `google_antigravity`: the retired
21 | frozen node@1.0 enum already contains a DIFFERENT member spelled `gemini_cli` (the retired
22 | personal-account CLI the operator directive §4.2/§14 forbids falling back to), so an
23 | ambiguous alias in permission logic is refused by not existing.
24 | * **The frozen schema was not touched.** node@1.0's `adapter` enum still has no member for
25 | either provider – that was U227, and this unit recorded it rather than editing a frozen
26 | artifact or fabricating a false member. OP-12.1 (2026-08-01) later ruled it by SUCCESSOR
27 | schema: `node@1.1` carries the wider enum, `@1.0` is still byte-frozen, and the assertions
28 | below pin exactly that (see the U227 section at the foot of this file).
29 | * **Credential isolation** (operator directive §13): the worker env-scrub union already
30 | classifies `XAI_API_KEY` / `GEMINI_API_KEY` / `GOOGLE_API_KEY`; pinned here so it stays true.

1  """Phase 14C `.harness` (unit): the OpenCode coding harness + supervised presence/version gate.
2
3  Deterministic, no-subprocess proofs. The two load-bearing invariants are:
4  - §2.2/§2.3 – the real harness's child env carries NO provider credential and the run command
5    is pinned to a local `ollama/*` model, so a driven session can neither transmit a secret nor
6    reach a paid/cloud backend.
7  - invariant 2 – a harness is spawnable only with a supervisor-issued identity (no naked session).
8  `OpenCodeCliHarness.version()` (which would spawn `opencode`) is NEVER called here; only its pure
9  builders are tested. The live presence/version probe is in the integration suite.

1  """U330/U416/U332 – one write path, an abort path, and a gate that cannot be skipped.
2
3  The cold audit's M2 (2026-08-06): the store's `mutate_operational_task` opens a
4  `BEGIN IMMEDIATE` boundary that read/modify/write on a shared record needs, and **five of the
5  seven orchestration writers did not use it** – `create_task`, `update_task`, `open_debate`,
6  `post_debate_turn`, `close_debate` all read a record into Python, built a successor from that
7  snapshot, and blind-wrote it back through an `ON CONFLICT DO UPDATE` that overwrites whatever
8  landed in between. Two nodes posting a turn to one debate is the ordinary case, not the exotic
9  one, and the loser's turn vanished with no conflict record – the silent last-write-wins
10 invariant 13 forbids.
11
12 Three properties are tested here, and the third one is why the first two are not enough:
13
14 1. **the fence exists** (§1) – the store's create/mutate entry points, and the absence of the
15   blind ones. Structural: it says the bypass is not merely unused but unreachable.
16 2. **the successor is computed INSIDE the fence** (§2) – a competing writer commits between
17   the service's read and its write, and its work survives. This is the property that
18   actually fails on the shipped-before code, and it fails for `{**snapshot, ...}` even if
19   that snapshot is written through a transactional method: routing the *call* through the
20   fence while still building the record from a stale read looks identical in a diff and
21   loses the same turn.
22 3. **the rules the fence now guards are re-asked inside it** (§2 also) – the round limit, the
23   close quorum and the update authority were all evaluated against the snapshot.
24
25 §3 is U416 (a debate whose participant can no longer answer had no terminal state but CLOSED,
26 which needs a turn from everyone – so it stayed OPEN forever) and §4 is U332 (an empty
27 `debate_ids` walked past the closed-debate gate, because the gate was a loop over the caller's
28 own list).
29
30 The genuinely concurrent falsification – two OS processes, not two threads – is
31 `tests/integration/test_operational_concurrent_processes.py`. It is the load-bearing one; these
32 are the fast, deterministic pins that say *which* property broke.

1 | """Governed node spawn FROM a per-pane picker selection (Phase 15E `spawn`, OP-7 §12.2/§12.3).
2 |
3 | The picker (`.picker`) only OFFERS options; this sub-step turns ONE selected option
4 | (provider × model × role) plus a mode (attended | autonomous) into a governed, supervised
5 | spawn – or a fail-closed refusal. These unit tests prove, without a live call:
6 |
7 | * frontier selections spawn through the REAL supervised path + the I-X3 SubscriptionGovernor
8 |   (allowance=2), and TEAR DOWN releases the count (D-LOOP-1);
9 | * local selections route through the ResidencyPlanner (invariant 22 – visible residency),
10 |  never through the subscription governor;
11 | * every fail-closed refusal: a greyed (unavailable) option, an un-offered role (I-SC1), an
12 |   unknown mode, a naked identity (invariant 2/29), a missing residency planner for a local
13 |   model, an unregistered local model, a frontier selection with no subscription;
14 | * attended and autonomous nodes are BOTH governed through the same supervised path – the mode
15 |   is chrome, never an authority grant (invariant 1);
16 | * the pane chrome's model badge is carried verbatim from the picker option (no divergent
17 |   re-resolution).

1 | """Governed live model PROBE emitter (Phase 17A `roundtrip`).
2 |
3 | The probe is the only live call the launch path makes, so it is gated like one and bounded like one.
4 | These tests pin that with zero live calls (the probe function itself is injected):
5 |
6 | * a CONCLUSIVE cached record short-circuits everything – no gate mutation, no terminal, no tokens;
7 | * a fresh probe runs only behind the same chain the conductor launch runs (live-operation
8 |   authorization → R8 §6 operator terms → `claude` present) and holds ONE durable I-X3 terminal
9 |   while it runs, handing it back in every path (D-LOOP-1);
10 | * a durable count already at the allowance REFUSES – a probe never becomes a third terminal;
11 | * an INCONCLUSIVE result is never cached (an auth/rate accident must not freeze into the launch
12 |   path) and never demotes the operator's selection;
13 | * `--ledger-only` is the offline contract the ticket emitter relies on: it reports what is
14 |   recorded and spends nothing.

1 | """Phase 18E `.live.shape` – U305: what a provider's real `-p --output-format json` document
2 | actually LOOKS like, measured rather than assumed.
3 |
4 | U238 hole 2 was closed at 18E `.hardening` by making acceptance read
5 | `extract_provider_response_field` – a RECOGNISED response field or nothing. That closure carried an
6 | open assumption, recorded as U305 and stated in `accept_probe`'s own docstring: **neither provider's
7 | real document had ever been read against that reader.** If a CLI nests its answer
8 | (`{"response": {"text": ...}}`) or emits content blocks, the strict reader returns `` and acceptance
9 | REFUSES a genuine live reply. The refusal direction is the safe one, and the ordering was ordered –
10 | but a live acceptance leg that concluded "the provider did not answer" from it would be reporting a
11 | reader defect as a provider fact.
12 |
13 | `describe_provider_document` is the instrument that answers it. It reports the document's STRUCTURE
14 | – key names, value types, dotted paths, where the probe token sits, and whether the strict reader
15 | can see it – and never its VALUES. That is a credential-isolation property (§2.2/§13), not a
16 | convenience: a shape record is published as evidence, and a describer that copied string values
17 | would publish whatever the CLI put in them.
18 |
19 | It also emits a `skeleton`: the same document with every string leaf replaced by a length
20 | placeholder, EXCEPT strings carrying the probe token, which become the token itself. The skeleton is
21 | therefore a replayable fixture of the real document's shape – the strict reader run against it
22 | answers the same question it answered against the original – with no model prose and no
23 | credential-bearing value in it.

301 | # -----
302 | # THE MEASUREMENT. U305 answered, 2026-08-02, by the governed live probe of both providers
303 | # (docs/evidence/live/phase18e_probe_document_shape_20260802T0230Z.json).
304 | #
305 | # These two documents are the `skeleton` fields of the real run – the real shapes with every string
306 | # value replaced by its length and the probe token preserved where the CLI put it. Nothing in them
307 | # is model prose and nothing is credential-bearing; that is what the describer's leaf-value-free
308 | # contract buys, and it is what makes a real document safe to keep as a fixture.
309 | #
310 | # PROVENANCE, exactly, because "verbatim" was claimed here and was false in one byte (round-1
311 | # gate-validator MAJOR-2 / spec-auditor MAJOR-1):
312 | # * the Antigravity fixture IS byte-for-byte the skeleton in `..document_shape_20260802T0219Z.json`
313 | #   – every string in that document is non-empty, so the S1 blank-string defect could not touch
314 | #   it – EXCEPT that the real `response` was `GEMINI_PROVIDER_OK\n` and token substitution
315 | #   replaces a token-BEARING string with the bare token, dropping the trailing newline. That is
316 | #   the skeleton working as designed and it is why the assertion below is containment, not
317 | #   equality (spec-audit MINOR-2);
318 | # * the Grok fixture matches the skeleton in `..grok_default_mode_20260802T0224Z.json` (the
319 | #   post-fix rendering). The FIRST artifact, `..document_shape_20260802T0219Z.json`, was written
320 | #   BEFORE the S1 fix and its grok skeleton therefore reads `text: "<str:0>"` – the defect
321 | #   itself, published. That artifact is preserved unaltered and corrected in place by
322 | #   `docs/evidence/live/phase18e_probe_document_shape_20260802T0219Z.CORRECTION.md`; the two
323 | #   runs' documents are structurally identical apart from that field.
324 | # -----
325 | GEMINI_TOKEN = "GEMINI_PROVIDER_OK"
326 |
327 | #: `agy --mode plan -p ... --output-format json`, measured. A flat `response` key: the shape the
328 | #: strict reader was built for. This probe was ACCEPTED and deserved to be.

1 | """Phase 17D `.events` – the approval drawer is sourced from REAL SESSION EVENTS ONLY (finding F2).
2 |
3 | The operator opened the shipped shell and saw three pending items – `ap-1` plan, `ap-2` protected
4 | action, `ap-3` clarification – that no session had produced. They were the 16D `.approvals` emitter's
5 | DETERMINISTIC DEMONSTRATION trio: a canned objective run through the real flow and two canned commands
6 | run through the real broker, rebuilt identically on every fetch. Real authority path, canned content
7 | (F2). This module replaces that producer: the drawer is rebuilt from the append-only log of events the
8 | running session actually produced, and an empty session shows an EMPTY drawer.
9 |
10 | What the tests below pin, in order of how badly each would hurt if it regressed:
11 |
12 | * **No events an empty, honest drawer** (`badge_count:0`, `demo_items:false`) – never the trio.
13 | * **The shell does not get to say what an event MEANS.** A recorded utterance is re-routed through
14 | the REAL `ConductorVoiceBridge` router + the REAL `CommandBroker`; the recorded classification must
15 | match what the classifier says now, or the whole feed fails closed. So the least-trusted surface
16 | (the renderer/main process) cannot promote an ordinary sentence into a protected-action row, nor
17 | demote a protected verb into a clarification, nor invent a row with no utterance behind it.
18 | * **A recorded plan cannot assert its own approvability** – it is DERIVED from the recorded
19 | `gate@1.0` verdict through the same `build_plan_proposal` the 15E surface uses, and the record is
20 | re-validated against the frozen `gate@1.0` schema (invariant 16: a failed gate is not approvable,
21 | and there is no override path).
22 | * **The operator's decisions PERSIST** – a resolve is itself a recorded event, replayed through
23 | `ApprovalQueue.resolve`, so authority (invariant 1) and the no-override rule (invariant 16) are
24 | re-enforced on every rebuild and a decided item stops appearing in the drawer.
25 | * **Fail closed on anything malformed** – unknown kinds, bad shapes, a decision the authority would
26 | refuse: the feed is `sourced:false` with a reason, never a partial or fabricated drawer.

1 | """phase-15a.statusbar – pin the status-bar view model's JS constants to their Python authorities.
2 |
3 | The status-bar view model (terminal/statusbar/statusbar-model.js) necessarily re-declares two
4 | values in JS that are authoritatively owned in Python:
5 | * LIVE_PROVIDERS ← control_plane/nodes/picker.py `registered_frontier_providers()`
6 | * SUBSCRIPTION_CAP ← node_runtime/supervisor/subscription_governor.py `MAX_ALLOWANCE` (OP-6)
7 |
8 | A comment linking them is not enough: if a future operator ruling changes the authorized provider
9 | set or raises the governor cap (both code changes), a stale JS mirror would MISREPRESENT the
10 | authorized scope in the shell status bar – for the cap, an UNDERSTATEMENT of the real ceiling. These
11 | tests parse the literals out of the JS source and assert they equal the Python authorities, so the
12 | mirror cannot silently drift (spec-audit MINOR M1/M2). This is a structural pin, not a runtime dep.
13 |
14 | **Which authority (18B `scope`).** The provider pin used to read
15 | `live_authorization.AUTHORIZED_PROVIDERS`. OP-12 made those two sets differ: four ids are now
16 | covered by a recorded operator ruling, but only two can be SELECTED in a pane and therefore only
17 | two have a subscription counter to render. Pinning the bar to the wider set would have demanded a
18 | `grok_build` counter for a provider no pane can spawn – advertising a lease the product cannot
19 | take. The pin now tracks the picker's frontier registration set, so it goes red exactly when the
20 | 18B picker sub-step wires the new providers and the JS mirror is not updated with it.

1 | """Durable I-X3 terminal-lease ledger (Phase 17A `.lease`).
2 |
3 | Until now the subscription governor (`SubscriptionGovernor`) was purely IN-PROCESS: every bounded
4 | emitter built a fresh governor, acquired, and released at teardown, so a terminal held by the
5 | LONG-LIVED shell (a real interactive `claude` session in pane 1) could never be counted. 17A needs a
6 | live session that OUTLIVES the emitter that gated it – so the count has to outlive the emitter too,
7 | or the I-X3 cap becomes decorative.
8 |
9 | These tests pin the durable ledger's contract, all deterministic and fail-closed:
10 |
11 | * a lease survives the process that took it (it is a file record, not memory);
12 | * the OP-6 allowance is enforced ACROSS processes – the (allowance+1)-th acquire is refused with
13 |   `SubscriptionLimitExceeded`, and the governor's `MAX_ALLOWANCE` cap is re-asserted here so no
14 |   caller can widen concurrency by passing a bigger number;
15 | * a lease whose HOLDER PROCESS IS DEAD is reaped – a crashed shell never wedges the count
16 |   (fail-closed the other way would be a permanent denial of the operator's own subscription);
17 | * acquire is idempotent per (subscription_ref, node_id) – a re-run of the same governed spawn
18 |   re-uses its lease instead of double-counting;
19 | * `seed_governor` projects the durable live leases into an in-process `SubscriptionGovernor`, which
20 |   is how the emitter's gate chain sees terminals held by OTHER processes;
21 | * release is by lease id (and by node), idempotent, and never touches another holder's lease;
22 | * the ledger file is the only state; a corrupt/absent file reads as EMPTY but a corrupt file is
23 |   never silently overwritten with a fabricated count – it fails closed on read.

384     # U111 – DIAGNOSTIC SCOPE: a redirected ledger writes its own records but COUNTS the durable ones
385     # -----
386     # Opened at 17B `spawn` (spec-audit MINOR-8) with 17E named as owner, and found again by the 17E
387     # spec-auditor (F1) with the exposure doubled: the fully-live run holds TWO live frontier terminals
388     # on the operator's subscription while `SOW_TERMINAL_LEASE_LEDGER` points at a per-pid scratch file,
389     # so for that window the real governor counts ZERO – and an operator shell already at its allowance
390     # of 2 could bring the true total to 4. The redirection itself is right: a check must never adopt or
391     # release a terminal the operator's own shell holds. What was missing is the other half – the cap has
392     # to be enforced across BOTH holder classes. So a redirected ledger is a DIAGNOSTIC one: it writes
393     # only its own scratch records, and it counts the durable ledger's live leases as a read-only
394     # baseline it can see but never touch.

1 | """Phase 18D – the U227 boundary moved, and the sentences that described it must move with it.
2 |
3 | **Why this file exists.** OP-12.1 (2026-08-01, `AUTONOMOUS_BUILD_DIRECTIVE.md` §17.1) resolved U227
4 | by successor schema: `node@1.1` admits `grok_build`, `google_antigravity` and `ollama_local`, and
5 | `NodeRegistry.register` accepts them. Before that ruling, roughly a dozen files across the product,
6 | the tools, the tests and the operator-facing config template explained themselves with sentences
7 | like *"U227 is operator-reserved"*, *"no schema-valid node RECORD can name them"*, and – worst –
8 | *"that check could never pass for either provider and never will"*.
9 |
10 | The 18D work commit corrected nine of them and its message claimed *"all nine places it lived"*.
11 | The gate-validator found **seven more** (MAJOR-1), three of which had become flatly false, including
12 | `tools/providers/run_frontier_providers.ps1`'s operator-facing help text and a docstring 50 lines
13 | above the corrected text in the SAME file. The spec-auditor independently found the same class in
14 | `config/live_operation.example.json` – the file an operator reads while deciding whether to
15 | authorize live operation, whose own comment invokes invariant 1 ("final authority has to be
16 | INFORMED authority") as its warrant for being accurate.
17 |
18 | So: a hand-count of prose sites is not a mechanism, and this repo's standing rule (U275, written by
19 | this very phase at 18B `picker`) is that a claim with no red-able test is a defect. This is the
20 | detector. It does not forbid the old words – a correction that QUOTES what it is correcting is the
21 | most honest form, and several of the fixes do exactly that. It requires that any live surface still
22 | carrying a pre-ruling claim ALSO names the ruling that overturned it, within sight of the claim.
23 |
24 | **Deliberately out of scope:** `docs/` (evidence reports, checkpoints, registers and receipts are
25 | append-only records of what was true when written – rewriting them is the drift, not the fix),
26 | `docs/canonical/` (frozen), and the FINAL_*.md reports (historical, and they predate the ruling).

1 | """U292(a) / U283 on the pane-worker emitter – the two gate inputs this module may not invent.
2 |
3 | Directive §17.2(3) sends the `gates.operator_terms_confirmed` parameter default here for "the
4 | U283-style closure", and the same closure covers its twin on the same signature, because they are
5 | one defect with two spellings: `build_worker_launch_ticket` answered two questions that are not
6 | its to answer.
7 |
8 | * `profile_loader: ProfileLoader | None = None` fell back to
9 | `ProfileLoader(DeploymentProfile("cloud"))`. Which deployment profile is in force is the HOST's
10 | fact. Manufacturing `cloud` made invariant 20's air-gap half **structurally unreachable on the
11 | product path** – the shell could open a frontier pane on an air-gapped host, and every test
12 | that "covered" the air-gap injected the loader the product never passed. That is U91's shape,
13 | found by both reviewers on `provider_probe_session` at 18C `probe-path` and closed there
14 | (U283); this module was the surface U292(a) recorded as still carrying it.
15 | * `operator_terms_confirmed: bool = True` published `gates.operator_terms_confirmed: true` in
16 | every ticket while no production caller supplied it – a PARAMETER DEFAULT rendered as a
17 | measurement. The 18C receipt had to disclose exactly that in `scope_note_gate_map` and exclude
18 | the gate from its verdict. That is U98's shape.
19 |
20 | Both are now REQUIRED keywords, and `main()` – the sole production caller – supplies each with its
21 | authorizing artifact named at the call site. These tests fail if either default comes back.
22 |
23 | Zero live calls, zero host dependence: no test here spawns anything or reads a real switch.

1  """Worker-pane refusals name the GATE that refused, and the VRAM messages state the cause they saw.
2
3  Both come out of the 2026-07-26 gate-validator re-validation of 17B `ticket`:
4
5  * **BLOCKING-1c** – the in-Electron receipt's "invariant 22 admission gate refused an over-budget
6    pane" leg asserted `VRAM|residency|displacing/i` against the refusal prose. An enumeration CRASH
7    whose message happened to contain "VRAM" satisfied it, so the leg went green while proving
8    nothing about invariant 22. Every refusal now carries a machine-readable `gate` id, the ticket
9    reports it as `refused_by`, and the legs assert THAT – an id cannot be borrowed by another gate.
10 * **BLOCKING-1a/b** – a `None` planner means the budget could not be ESTABLISHED (daemon
11   unreachable, or a budget the host's own residency falsified). That is not "your model does not
12   fit"; reporting it as such sends the operator hunting for VRAM they already have.
13 * **MINOR-1** – one message asserted "would only fit by displacing another resident model" for
14   every over-budget case, including ones where nothing is resident at all.
15
16 Zero live calls, zero host dependence: the planner and the gates are injected.
17 """

1  """Phase 18E `live.electron.wiring` – a supervised worker PANE becomes a Sovereign node RECORD.
2
3  Directive §17.2(1) asks the live acceptance leg for "a supervised ConPTY pane **as a registered
4  Sovereign node**". 18D wired that for the one-shot `GovernedProbeSession` and for nothing else: a
5  picker selection that opens a real `grok`/`agy` pane on the operator's host produced a durable I-X3
6  lease, an argv and a chrome – and no node record at all. Invariant 2 says every terminal is a
7  Sovereign node; the pane path was the terminal with no node.
8
9  These tests pin the wiring that closes it, end to end and on the REAL modules (real `NodeRegistry`,
10 real hash-chained `AppendOnlyEventLog`, real schema files, real jsonschema validator, real ticket
11 emitter). Only the filesystem location (tmp_path), the host detections the emitter already injects,
12 and the CLI binary that is never executed are stood in for.
13
14 The lifecycle is THREE facts written at the three moments they become true, never one moment
15 asserting all three:
16
17 1. **ticket time** – the governed chain passed and a terminal was counted, so a record is written
18   in `SPAWNING`. That is the honest state: authorized, not yet born. If the registrar refuses,
19   the SESSION is refused and the durable terminal is handed back (18D's rule – a leased terminal
20   with no record is the naked-but-leased session the chain exists to prevent);
21 2. **spawn time** – the shell has a supervised ConPTY with a live pid, and only then does the
22   record move to `READY` carrying that pid. Nothing before this claims the process exists;
23 3. **release time** – the session ended, so the record is CLOSED on the same append-only log
24   (`transition` → `exit`, D-LOOP-1 in the one place an auditor would look).
25
26 Steps 2 and 3 happen in a DIFFERENT PROCESS from step 1 (each emitter invocation is its own
27 `py -3.12`), so they rest on reading the durable log back – which is why `NodeRegistry.rehydrate`
28 and `ProviderNodeRegistrar.adopt_from_log` exist and are tested here as the fail-closed things they
29 are, not as conveniences.

1  """Governed LIVE WORKER pane authorization (Phase 17B `.ticket`; directive $16 track 17B, U70).
2
3  16B wired the per-pane picker's READ path and RECORDED a selection; nothing was ever born from it
4  (`governed:false`, `selected_awaiting_governed_spawn`) – the operator's first-use finding F3: "a
5  picker selection records + badges but launches nothing". 17B `.ticket` builds the authorization half:
6  one picker selection → the SAME gate chain the conductor pane runs → an executable interactive launch
7  spec, or a fail-closed refusal.
8
9  What these tests pin, with ZERO live calls:
10
11  * the selection guard is the ONE shared authority (`pane_node_spawn.assert_selection_spawnable`):
12    greyed option, unknown mode, unoffered role, conductor role, naked identity are all refused
13    BEFORE any gate/governor/planner mutation;
14  * a frontier worker runs the full live chain – profile/roster + LIVE_OPERATION_AUTHORIZED,
15    provider-live, R8 $6 operator terms, CLI presence, I-X3 acquire – and yields an INTERACTIVE argv
16    (no `~p`, no `codex exec`), never a headless one-shot;
17  * a LOCAL worker is NOT subscription-governed (invariant 19/22): no I-X3 count, no live gate, but
18    it MUST route through the ResidencyPlanner and is refused when VRAM cannot be proven to fit;
19  * the chrome is carried VERBATIM from the picker option (invariant 3 – a badge can never diverge
20    from what the operator selected) and `model_verified` is never upgraded here;
21  * D-LOOP-1: `teardown()` releases a frontier terminal and is a no-op for a local node.

1  """Claims the worker launch ticket makes about ITSELF have to be true.
2
3  Every case here is a finding from the 2026-07-26 independent gate-validator pass and spec-audit of
4  17B `.ticket`, where a statement in the code or the ticket was not delivered by the code under it:
5
6  * `exe = resolved or "claude"` – a fail-OPEN under the module's own claim that "the shell spawns
7    exactly what was gated": with presence injected and detection empty, the ticket carried a bare
8    binary NAME for the shell to PATH-search (spec-audit MINOR-4).
9  * `chrome.node_state = "ready"` on a frontier authorization where nothing has spawned – a live-node
10    state asserted about a node that does not exist, in the same ticket that says
11    `containment.supervisor_bound: false` (spec-audit MINOR-1).
12  * `governor_released` documented "measured, not asserted" while the refusal branch read the node id
13    off a ticket whose `identity` is null: the comparison used a sentinel that can never be a holder,
14    so it was vacuously true on exactly the branch where a leak is possible (spec-audit MINOR-5).
15  * `_assert_option_offered` took the FIRST identity match, assuming the identity fields key an
16    option – true on today's roster, asserted nowhere (spec-audit MINOR-6).
17  * the enumeration-fault gate id (`host_enumeration`) exists so an enumeration crash cannot read as
18    another gate firing, and had no test (validator MINOR-2).
19
20  Zero live calls, zero host dependence.

1  """The worker launch ticket reports WHICH gate refused (`refused_by`), machine-readably.
2
3  Why the field exists (gate-validator BLOCKING-1c, 2026-07-26): the in-Electron receipt proved its
4  fail-closed legs by regex-matching the refusal PROSE. An enumeration crash whose message contained
5  the word "VRAM" satisfied the leg that was supposed to prove the invariant-22 admission gate – the
6  leg was green and proved nothing. A gate id cannot be borrowed that way, so each leg now asserts one.
7
8  These tests pin the mapping the legs depend on. Every gate is driven through the real
9  `build_worker_launch_ticket` with injected dependencies – no live call, no host dependence.

1 | """Phase 14E assembled product-level validation harness (directive §9 table 14E).
2 |
3 | The assembled run stands up one conductor + one frontier worker + one OpenCode/local coder
4 | worker + one local reasoning worker over live shared MCP, then exercises succession, a bounded
5 | debate, a gated coding task, and full restart+recovery. This package holds the harness; it
6 | degrades HONESTLY (directive §10.4) to whatever subset proved live and records exactly which
7 | legs were LIVE vs MOCK vs DETERMINISTIC-SUBSTITUTE – it never presents a substituted result as
8 | a real-provider result.
9 | """
```

```

1  """Phase 14E ``.roster`` – assembled-system roster + honest liveness matrix + item-7 Ollama smoke.
2
3  Phase 14E is product-level validation: one assembled run of a conductor + a frontier worker + an
4  OpenCode/local coder worker + a local reasoning worker over live shared MCP. This module is the
5  FIRST 14E sub-step. It does two things, both deterministic and fail-closed:
6
7  1. Composes the four assembled ROLES from the existing governed roster (`adapters/roster.py`)
8     plus the Phase-4 conductor path, and classifies each leg HONESTLY as LIVE, MOCK, or
9     DETERMINISTIC_SUBSTITUTE with the exact reason. This is the "which legs proved live vs
10    mock/deterministic" evidence the directive (§10.4) requires the assembled run to report –
11    produced here once, up front, so ``.run`` cannot silently overclaim a leg.
12
13    2. Re-runs the on-host Ollama smoke (STATUS_RECONCILIATION item 7) that was artifact-attested
14    at the completion audit but explicitly deferred to 14E on-host: a real model list, a real
15    tiny generate, and its measured latency – recorded, never faked. If the daemon is not
16    reachable the smoke degrades honestly (available=False) rather than fabricating a result.
17
18    Prohibitions still bind: no live frontier call here (owed / skip-with-record at 14B); no
19    credential handling (§2.2) – a role carries only an MCP identity/subscription REFERENCE, never a
20    token; local Ollama is permitted (§2.4 allows a detected local model, no credentials involved).
21    """

1  """Phase 14E `.run` – the single assembled end-to-end scenario over LIVE shared MCP.
2
3  Consumes the `.roster` liveness matrix (`roster_report.assembled_report`) as the SINGLE source of
4  which legs are LIVE vs MOCK vs DETERMINISTIC_SUBSTITUTE – no leg is upgraded here beyond what
5  `.roster` proved. Then drives one assembled run over a REAL MCP server:
6
7  1. a governed coding task CANDIDATE → node-local gate → controlled merge → ACCEPTED (promoted by a
8     DIFFERENT gate node, invariant 18) across the assembled roster;
9  2. one bounded debate (≤5 rounds, dissent preserved verbatim, cost-governed) requested by a
10     NON-conductor worker (invariant 18, Phase 7 §2.8);
11  3. conductor replacement mid-run (SuccessionManager: serialize → kill → reconstruct into a
12     DIFFERENT mock model, ZERO project loss, Phase 11);
13  4. full restart + recovery: the MCP process is stopped and restarted over the SAME durable store,
14     then the successor reconstructs again – the ACCEPTED artifact, the debate record, and the
15     succession snapshot all survive (zero project loss across a process restart).
16
17  Honesty (directive §6/§10.4): the rendered/visible panes are an operator-run metric (like the
18  Phase-1 spike and the 14A window) – this headless run proves the governed DATA path end-to-end
19  (MCP state, gate verdicts, provenance, succession, recovery). It does NOT claim a live `claude`
20  frontier call (owed at 14B) or a live local-coder LANDED edit (U31): the coding edit is a
21  deterministic seeded stand-in (`from_live_model=False`). The one leg that genuinely runs a real
22  model this session is the local reasoning Ollama receipt carried in the `.roster` report.
23
24  The UI-side recovery machine (terminal/recovery/*.js, RecoveryStore) is proven at gate/phase-14a
25  by the Node suite; this Python harness proves the corresponding governed DATA-path recovery (MCP
26  process restart + zero-loss conductor reconstruction), which is what a headless session can verify.

1 | \uFEFF""Phase 13 comparative evaluation harness (Plan Â§7-P13, Â§12.4).
2 |
3 | Runs the reference workload under four configurations and instruments cost-to-accepted-output
4 | plus a capability matrix, so the operator can see what the governance layers COST and what they
5 | BUY relative to simpler baselines:
6 |
7 |     C0_single_pass      â€” one model, one answer, no orchestration (ungated, no provenance).
8 |     C2_conductor_raw    â€” a conductor + raw workers; outputs accepted without gate/provenance.
9 |     C3_sovereign_no_debateâ€” full governance: workers publish CANDIDATE via MCP, a gate promotes
10 |                          to ACCEPTED (provenance + gate verdict), no debate.
11 |     C4_sovereign_debate â€” C3 plus a bounded evidence-based debate before the gate.
12 |
13 | HONEST LIMITATION (must be stated): all backends are DETERMINISTIC MOCKS, so every config
14 | produces the same content â€” this harness measures ORCHESTRATION cost and capabilities, NOT
15 | model reasoning quality. No claim is made that any config reasons better; a real model-quality
16 | comparison needs live/local models under the same harness (deferred, Track E).

1  """Measure every observable refusal on the collaboration path BEFORE and AFTER the U326 fix.
2
3  This is the artifact behind §2 of `docs/evidence/PHASE19_UNIT2_U326_POLICY_DELEGATION_CHECKPOINT.md`.
4  It is TRACKED and pinned to an explicit base commit on purpose: the first version lived in the
5  gitignored `docs/loop/logs/` and read `HEAD:`, so the act of committing the fix turned it into a
6  comparison of the new module with itself and it reported "0 of 31 scenarios differ" – the
7  report's central quantitative claim, self-invalidated by being recorded. Found by both round-2
8  reviewers.
9
10 The base default is `b529314`, the commit before unit 19.2's work commit. HEAD's pre-unit
11 `collaboration_service.py` never called the policy object it held – that IS U326 – so importing
12 it beside the CURRENT `control_plane/policy.py` reproduces the pre-unit behaviour exactly.
13
14 Run from the repo root: py -3.12 tools/evaluation/u326_before_after.py [base-commit]

1  """APPROVAL-DECISION router emitter, over the session-event queue – Phase 17D `events` (OP-11 §16).
2
3  The operator's Approve/Reject on a drawer row routes back to the GOVERNED authority
4  (`ApprovalQueue.resolve`), self-authorizing nothing (invariant 1). This emitter is that route: it
5  rebuilds the queue from the SAME recorded session events the drawer was folded from (`--events`) and
6  calls `ApprovalQueue.resolve(item, operator, decision)`, which enforces operator-only authority
7  (invariant 1) and refuses an approve of a non-approvable item (invariant 16, no override path). The
8  shell (Node) never decides – it forwards `--item`/`--decision` and this Python authority resolves or
9  refuses.
10
11  On a RESOLVE the feed carries the `decision_event` the shell must append to its log – minted by the
12  authority that made the decision, so the shell never authors a decision record of its own, and so the
13  resolve PERSISTS: every later rebuild replays it through `ApprovalQueue.resolve` and the decided item
14  stops appearing in the drawer. A governed REFUSAL mints nothing (there is nothing to persist).
15
16  Still owed and stated on every feed (`side_effects_owed`): the downstream effect of an APPROVE – the
17  broker executing the queued command, `ObjectiveIntake` assigning an approved plan – is not fired from
18  this decide path.
19
20  No live call, no credential, no network, no MCP server (§2.2/§2.4, D-LOOP-1). A GOVERNED refusal is a
21  well-formed `resolved:false, refused:true` feed – honest, not a crash. A fault fails closed to
22  `resolved:false, unavailable:true`. `--emit-approval-decision` prints ONLY the feed JSON (one line).

1  """APPROVAL-DRAWER feed emitter, sourced from REAL SESSION EVENTS – Phase 17D `.events` (OP-11 §16).
2
3  The operator's drawer must show what THIS session produced and nothing else. Until 17D this emitter
4  built the drawer from a canned objective and two canned commands, so a freshly launched shell showed
5  three pending approvals nobody had asked for (finding F2). It now folds the shell's append-only
6  session-approval log (`--events <path>`, written by `apps/desktop/approvals/session-events.js`)
7  through `control_plane.orchestration.session_approvals`, which re-derives every row with the same
8  classifiers that decided it live. **No events  an empty drawer.** There is no path here that invents
9  a row; the retired demonstration builder now lives under `tests/support/demo_approval_queue.py`.
10
11  No log path (or a missing file) is the ordinary first-launch state – an empty session, emitted as an
12  empty drawer with `sourced:true`. Fail-closed (invariant 3 / invariant 20 spirit): a log that cannot
13  be read or re-derived in full  the unavailable feed (`sourced:false`, `reason`, empty drawer), a
14  0-exit JSON line the shell renders as "approvals unavailable", never a fabricated pending item.
15
16  Cheap and side-effect-free by construction (D-LOOP-1): re-deriving recorded events starts no MCP
17  server, no flow, no engine, makes no live call ($2.2/$2.4) and writes nothing.
18
19  `--emit-approval-drawer` prints ONLY the feed JSON (the stable shell contract, one line).

1  """Governed CONDUCTOR dispatch feed emitter – Phase 16C `.dispatch` (directive §15 track 16C; OP-8 §13.4).
2
3  The shell's govern-born conductor pane (`.spawn`) dispatches work to worker nodes over MCP and
4  synthesizes the results (OP-8 §13.4). This emitter runs ONE governed dispatch through the REAL
5  `control_plane.orchestration.live_flow` loop (decompose → assign BY DESCRIPTOR → CANDIDATE over MCP →
6  real gate engine → conductor synthesis into an acceptance packet) and prints the folded
7  `conductor_dispatch_feed@1.0` JSON the shell renders – the SAME bounded `py -3.12` read-source pattern
8  the 16B picker and the 16C `.selection`/`.spawn` feeds use.
9
10 MOCK-FIRST BY DEFAULT, no live call (directive §6 / §10.4): with no flag the dispatch runs on the
11 mock conductor + local workers (`legs.conductor=mock`, `legs.workers=mock`) and spawns NO
12 `claude`/`codex` process (§2.2/§2.4). That is the ONLY thing the shell's launch path asks for – an
13 app launch may never spend the operator's subscription – and the live-spawn imports live inside the
14 `--live-workers` factory so this module cannot reach a vendor CLI without the flag.
15
16 `--live-workers` (Phase 17B `.legs`) DOES spawn one governed live `claude_code` worker: every live
17 gate applies first (roster profile + LIVE_OPERATION_AUTHORIZED, provider-live, R8 §6 operator terms,
18 CLI presence, I-X3 acquire), the flow routes it exactly one subtask, and its leg is derived from the
19 checkpoint the CLI reports back – so `legs.workers=live` is reachable and U58's worker half is
20 discharged by evidence rather than asserted. D-LOOP-1: the loopback MCP server + flow are created in
21 a caller-owned tempdir and torn down before the feed is emitted (`torn_down:true`), and the durable
22 I-X3 lease is released on every path; nothing outlives the tool.
23
24 Fail-closed (invariant 3 / invariant 20 spirit): any fault the un-dispatched feed
25 (`dispatched:false`, `reason`), a 0-exit JSON line the shell renders as "dispatch unavailable", never a
26 fabricated dispatch.
27
28 `--emit-conductor-dispatch` prints ONLY the feed JSON (the stable shell contract, one line).

55
56 #: The LIVE worker's brief: the same smoke objective, plus the criteria the STAGE gate will apply to
57 #: whatever it publishes – a definition of done in the sense of Plan §9 (role + task + need-to-know).
58 #:
59 #: WHY (17E `.close`, measured): a live `claude` worker was given the bare objective, answered it
60 #: perfectly well, and the real stage gate refused the artifact because the prose contained one
61 #: informal incompleteness marker – `no_placeholders` is CRITICAL and scans the published bytes. The
62 #: node was judged by a rule nobody had given it, so whether the assembled leg came back green
63 #: depended on the model's word choice.
64 #:
65 #: WHAT THIS IS NOT (spec-audit M3/M4 at this gate, recorded rather than argued away):
66 #: * It is NOT scoped context routed over MCP. `ModelWorkerAdapter.execute` embeds the objective
67 #: verbatim into the published bytes, so this text becomes part of the artifact the gate scans.
68 #: That is why the "cannot self-defeat" test below has to exist at all.

```

```

69 #: * The evidence that this gate refuses live work – the 2026-07-31T15:13Z refusal run – was produced
70 #: under the BARE objective, i.e. the configuration BEFORE this constant. It is evidence about the
71 #: gate FUNCTION (unchanged, and pinned by the mock-path tests), not about this changed path. Under
72 #: the briefed configuration there is exactly one live run and it is green.
73 #: * `no_placeholders` is the only criterion here the node's wording can trip. `claims_cite_evidence`
74 #: evaluates the ADAPTER's generated claim records, not the model's prose, so the brief does not
75 #: tell the node it is judged on that (it used to; the sentence is gone).
76 #:
77 #: The marker words are DELIBERATELY not spelled out – quoting them here would trip `no_placeholders`
78 #: on every run, for the text of the instruction. `test_the_live_objective_states_the_stage_criteria`
79 #: and `cannot_self_defeat` pins that with the real criterion function.
80 LIVE_WORKER_OBJECTIVE = (
81     f"{DEFAULT_OBJECTIVE}. Answer in at most three sentences of complete, finished prose. "
82     f"What you publish is judged by a deterministic gate whose criteria are: "
83     f"{'', '.join(STAGE_CRITERIA)}. One of those binds your wording: the gate scans your text "
84     f"literally for informal markers of incomplete or provisional work (the blocklist in "
85     f"control_plane/gates/criteria.py) and refuses the artifact if it finds one, even in a "
86     f"quotation or an aside. Write only settled statements about the roster design itself."
87 )
88

92     return _dt.datetime.now(_dt.timezone.utc).isoformat()
93
94 #: Smoke-scale by CONSTRUCTION, not by this number: the governed loop routes exactly one `reasoning`
95 #: subtask to the single live node, so exactly one exchange happens (directive §16 "live exchanges
96 #: MINIMAL"). `max_tokens` is threaded through the adapter contract but `claude -p` accepts no such
97 #: flag, so `ClaudeCliBackend.generate` cannot enforce it – the only bound that actually binds a live
98 #: exchange is the wall clock below. Stated plainly because the earlier comment here claimed this
99 #: ceiling "keeps that exchange minimal", which it does not (spec-audit MINOR-4).
100 LIVE_WORKER_MAX_TOKENS = 200
101 #: The one bound that actually binds. `claude -p` is an agentic session, not a completion endpoint:
102 #: it may use tools before answering. Two `.legs` dispatches spent a real call and died at 150 s with
103 #: the node reporting `TimeoutExpired` (visible in the feed's `node_refusals` since this sub-step);
104 #: the runs that then succeeded took 254 s and 318 s. Those measurements are why 150 s was wrong –
105 #: 420 s is a chosen margin above them, a fail-closed ceiling on ONE exchange and not a target. Each
106 #: live run records the elapsed time it actually needed in the feed's `live_run` block.

1 | """Governed CONDUCTOR **launch ticket** – Phase 17A `.lease` (directive §16 track 17A; OP-8 §13/OP-9).
2 |
3 | The operator's first-use finding F3: conductor pane 1 sits at `awaiting_live_conductor` and typing
4 | into it gets no answer. That state is honest – `emit_conductor_spawn` runs the full live-gate chain
5 | but deliberately DEFERS the interactive `claude` drive and tears its I-X3 terminal down before
6 | emitting, so the shell gets gates without a session. 17A ends the black pane, and the first thing it
7 | needs is a shape the shell can actually *execute*:
8 |
9 | **a launch ticket** – an authorization decision made by the governed Python path (never by the
10 | shell), carrying the interactive argv, the NAMES of the credential-bearing env vars the shell must
11 | drop (§2.2 – names, never values), the CONDUCTOR chrome, and a **durable I-X3 lease that is still
12 | held when the ticket is emitted**, because the session it authorizes will outlive this emitter.
13 |
14 | Why the lease had to become durable (`node_runtime/supervisor/terminal_lease`): every bounded emitter
15 | in this build counts terminals in a fresh in-process `SubscriptionGovernor` and releases at teardown.
16 | That was correct while nothing live outlived an emitter. A real interactive `claude` in the shell's
17 | ConPTY does. Without a durable count the shell could hold two sessions while every emitter reported
18 | 0/2 – I-X3 would be decorative. So the ticket path:
19 |
20 | 1. seeds an in-process governor from the DURABLE live leases (terminals held by the shell or by
21 | another tool become visible to this process's gate chain);
22 | 2. runs `spawn_conductor_pane` – the identical gate chain 16C gated (live-operation authorization,
23 | provider-live, R8 §6 operator terms, `claude` presence, I-X3 acquire), with NO launcher;
24 | 3. takes the DURABLE lease for the conductor node, owned by `--holder-pid` (the shell's pid);
25 | 4. tears the in-process session down (the emitter's own D-LOOP-1 bookkeeping) – the durable lease
26 | is the ONLY thing that survives, it is named in the ticket, and `--release-lease` hands it back.
27 |
28 | Fail-closed everywhere (invariant 3 / invariant 20 spirit): any gate refusal, a durable count already
29 | at the allowance, or an unreadable ledger yields a REFUSAL ticket (`authorized:false`, `refused:true`,
30 | `reason`, no argv, no lease) – never a fabricated authorization, never a leaked lease. A lease is
31 | never taken without a real owner pid: `--holder-pid` is REQUIRED, because a lease owned by this
32 | about-to-exit process would count a terminal nobody holds.
33 |
34 | This emitter makes NO live model call and touches no credential: it builds argv and counts terminals.
35 | The actual ConPTY launch is the shell's (`.pty`), and the type-answer round trip is `.roundtrip`.
36 |
37 | Phase 17A `.pty` closed the three counting gaps `.lease` recorded as owed:
38 |
39 | * **U75** – the lease is keyed to the SESSION (`--session-id`), not to the constant conductor node
40 | id, so two real interactive sessions for pane 1 are two counted terminals;
41 | * **U76** – the durable count and the always-visible status bar now use the ONE
42 | `canonical_subscription_ref(provider)` spelling, so the bar cannot read 0/2 against a held lease;
43 | * **U77** – `--release-session` reclaims a lease by the key the SHELL chose before it asked, so a
44 | ticket whose delivery fails (shape refusal, timeout) does not strand a terminal.
45 |
46 | Modes (a governed refusal is still a 0-exit JSON ticket; usage/argument errors exit 2 with no JSON):
47 | --emit-conductor-launch --holder-pid <pid> --session-id <id> the launch ticket (or a refusal)
48 | --release-lease <lease_id> hand one durable terminal back
49 | --release-session <session_id> hand back the terminal held by one session
50 | --emit-lease-status the observable durable n/allowance count

1  """Authoritative CONDUCTOR selection feed – Phase 16C `.selection` (directive §15 track 16C; OP-10).
2
3  Closes **U65**. The shell renders pane-1's CONDUCTOR badge + Resume>Select control. Until now it
4  read those from hand-maintained literals in `apps/desktop/main.js` that MUST mirror
5  `control_plane.conductor.selection.OPERATOR_SELECTED_CONDUCTOR` – a drift risk the register flagged
6  (U65): a copy the operator's authority could silently disagree with.
7
8  This tool is the ONE authority the shell sources from instead. It imports the operator's conductor
9  SELECTION and the succession affordance from their canonical modules and emits them as a stable JSON
10 contract (`conductor_selection_feed@1.0`). The shell renders exactly what Python holds; the two can
11 no longer drift. This mirrors the 16B picker read-source pattern (`enumerate_pane_picker --emit-picker`
12 → `apps/desktop/picker/source.js`): the option/record set is produced by ONE Python authority and
13 rendered verbatim by the shell.
14
15 Honesty (invariant 3, §6/§10.4): the feed is the honest PRE-LAUNCH binding – the selection LABEL
16 ("fable-5"), `executing.model` None, `verified` False. Nothing has executed yet; a live checkpoint is
17 recorded only when a live reply reports one (that is the later `.spawn`/`.dispatch` work). Read-only:
18 the executed path makes no model call, no credential access, no network (§2.2/§2.4) – it imports two
19 records via their canonical modules and prints them. (The succession affordance is imported from
20 `conductor_pane_spawn`, whose transitive import graph is heavier than these two leaf records; that is
21 an import-graph shape, not a runtime call – U71 tracks relocating the pure builder to a leaf module.)
22
23 `--emit-conductor-selection` prints ONLY the feed JSON (the stable shell contract, one line).

```

1 | """Governed CONDUCTOR spawn feed – Phase 16C `.spawn` (directive §15 track 16C; OP-8 §13 / OP-9).
2 |
3 | The shell's pane 1 is the conductor-first CONDUCTOR node (§12.4). Until `.selection` it drew its
4 | badge from a hand-maintained literal (U65, closed); until THIS sub-step the pane was a pure JS
5 | placeholder that never touched the governed spawn path – the on-launch pane 1 was not *born* through
6 | `node_runtime/supervisor/conductor_pane_spawn.spawn_conductor_pane` and its `node_state` string was a
7 | hardcoded constant. `.spawn` ends that: the shell sources the conductor pane's governed spawn from
8 | THIS emitter, so pane 1 is GOVERNED-BORN through the full live-gate chain
9 | (`ProfileLoader.assert_startup` + `LiveAuthorization.assert_provider_live` + R8 §6 operator terms +
10 | `claude` CLI presence + the I-X3 `SubscriptionGovernor`), exactly as a live worker pane is.
11 |
12 | SUBSTITUTION (directive §6, recorded): this is a bounded one-shot subprocess emitter – the SAME
13 | `py -3.12` read-source pattern the 16B picker and the 16C `.selection` badge use – NOT the WS-IPC
14 | channel. It runs the governed spawn with NO launcher, so the real interactive `claude` ConPTY drive
15 | is DEFERRED to the operator-run shell (`spawn_conductor_pane`'s documented deferred branch): a live
16 | model call is never made here (§2.2/§2.4), and `node_state` is the honest `awaiting_live_conductor`
17 | – gates passed, argv + credential-scrubbed env built, I-X3 counted – but no session attached yet. The
18 | mock-first "ready" branch (a launcher injected `node_state: ready`) is proven by the unit tests and
19 | `build_conductor_spawn_feed(..., launcher=...)`; the shell contract emits the deferred governed spawn.
20 |
21 | D-LOOP-1 (CRITICAL, directive §14): the governed spawn ACQUIRES one I-X3 terminal; this emitter tears
22 | it down (`ConductorPaneSession.teardown()`) in a `finally` BEFORE emitting, and records the release
23 | (`torn_down` / `governor_released`) so a reader can verify no live terminal outlives the tool. With no
24 | launcher nothing is actually launched, so teardown only releases the counted terminal – a live
25 | `claude` process is never started here in the first place.
26 |
27 | Honesty / fail-closed (invariant 3, invariant 20 spirit): if any gate REFUSES (no live-operation
28 | config, provider not live, operator terms unconfirmed, `claude` absent, naked identity, I-X3 full)
29 | this emits a governed-REFUSAL feed (`spawned:false`, `refused:true`, `reason`, `node_state:
30 | spawn_refused`) – NEVER a fabricated spawn. `operator_terms_confirmed=True` rides the RECORDED OP-9
31 | determination (the operator made it, not the loop – invariant 1); it is not a credential.
32 |
33 | `--emit-conductor-spawn` prints ONLY the feed JSON (the stable shell contract, one line).

1  """Conductor voice-IN feed emitter – Phase 16E `engine` (directive §15 track 16E; OP-8 §13.5).
2
3  The shell's talk button must route captured operator speech through the REAL `ConductorVoiceBridge`
4  and surface the outcome (delivered chat / queued protected action / clarify) with a VISIBLE mock-engine
5  indicator – closing the READ half of U67. This emitter builds the engine-selected bridge over a REAL
6  `CommandBroker`, routes ONE captured utterance (an `--audio-ref` stand-in – real PCM is operator-run),
7  and prints its outcome folded into the stable `conductor_voice_feed@1.0` JSON the shell renders – the
8  SAME bounded `py -3.12` read-source pattern the 16B picker and the 16C/16D feeds use.
9
10 MOCK-FIRST, no live call (directive §6 / §10.4): the bridge runs the mock STT + a local broker, so
11 `--emit-conductor-voice` NEVER spawns a `claude`/`codex` process (§2.2/§2.4). NO TTS (I-V2/D-VOICE-02):
12 `tts:False` is carried through. Audio is transcribe-then-discard (invariant 26). Fail-closed
13 (invariant 3): any fault the unavailable feed, a 0-exit JSON line the shell renders as "voice
14 unavailable", never a fabricated "delivered to the conductor".
15
16 `--emit-conductor-voice [--audio-ref <ref>]` prints ONLY the feed JSON (the stable shell contract, one
17 line).

85 |     is itself fail-closed; this only guards a parse/setup fault.
86 |
87 |     Phase 17C `.probe`: on the STAND-IN path `blocking=False`. That ref carries no PCM, so
88 |     `select_engine` ALWAYS lands on the mock here – a blocking WSL probe buys a strictly unused answer
89 |     and charges the operator 7–22 s (up to the 90 s budget) for it on every talk press. The Python probe
90 |     cache is module state in a process that exits after one emission, so it can never be warmed by the
91 |     shell's background probe either. Engine AVAILABILITY is the shell-side `VoiceProbe`'s maintained
92 |     fact; this feed reports the engine that handled THIS utterance and, on the non-blocking read, an
93 |     honest `nemo_state:"unprobed"` rather than a fresh (and unused) verdict.
94 |
95 |     Phase 17C `.mic`: with `--real-capture` the ref is a real WAV of the operator's speech, so the real
96 |     engine is both reachable and REQUIRED – `for_capture=True`, and `blocking=True` so that a host
97 |     whose answer was not seeded establishes it properly instead of silently mocking real speech. A

1 | """Emit the OP-12 provider NODE-REGISTRATION report – Phase 18D `.close`.
2 |
3 | **What this measures, and the one substitution it makes.** OP-12.1 authorized the successor schema
4 | `node@1.1`; 18D `.amendment` shipped it and wired nothing to it; `.close` wired
5 | `provider_probe_session` → `ProviderNodeRegistrar`. The leg that would prove the wiring end to end
6 | on the operator's own host is a LIVE probe, and its entry condition is the operator's (their CLI
7 | logins, and their own edit to the never-committed `config/live_operation.json`, which on this host
8 | still cites OP-6 – so both OP-12 providers are DENIED). Directive §17 says an unmet entry condition
9 | is skip-with-record; directive §6 says substitute the nearest faithful equivalent and RUN THE FULL
10 | GOVERNANCE PATH around it.
11 |
12 | **What is injected, ALL of it, because the first version of this note said "exactly one thing" and
13 | that was false** (spec-audit MAJOR-1 – a claim about the gate chain that concealed which gates the
14 | report had answered for itself):
15 |
16 | 1. the **live-operation switch** – a FIXTURE config written into a scratch directory and read by
17 | the REAL loader, so it goes through the same parsing and the same code-pinned scope check the
18 | operator's file does. This is the substitution §17/§6 permit;
19 | 2. **CLI presence** (`cli_present=True`) and the executable – a scratch path that is never
20 | spawned. Nothing is executed, so nothing is detected;
21 | 3. the **I-X3 ledger** – a scratch `TerminalLeaseLedger`, so the operator's durable one is never
22 | written. The allowance still comes from the code-pinned map (1 per OP-12 subscription, never
23 | the fixture's `terminals_per_subscription`), and the report asserts that;
24 | 4. the **holder pid**, which is this process.
25 |
26 | What is NOT injected, and is the reason this report means anything: the **deployment profile** comes
27 | from the host through `profile_loader_from_host()` – so on an `offline_airgapped` host this report
28 | REFUSES exactly as the product path would (invariant 20's air-gap half, which a self-manufactured
29 | `cloud` loader made structurally unreachable – U91's shape, and this file had it) – and the
30 | **operator's R8 §6 terms determination** is the recorded one at directive §17, cited at the call
31 | site, not a default. Everything else is the product: the real `governed_probe_session` and the rest
32 | of its gate chain, the real `NodeRegistry`, the real hash-chained append-only log, the real schema
33 | files, the real jsonschema validator. No credential is read (§2.2). The operator's real ledger and
34 | real node log are never opened: this report MEASURES that by content hash, before and after.
35 |
36 | The real switch is read too, read-only, and reported beside the fixture one – so a reader can see
37 | both that the wiring works and that the operator's world still refuses these providers.
38 |
39 | Contract (stdout, one JSON document, exit 0 unless the report itself could not be produced):
40 | `{schema, generated_at, vocabulary, real_switch, fixture_scope, registrations{provider→...},
41 | refusals{...}, durable_store{...}, ok, notes}`.

1 | """Governed SUBSCRIPTION-STATUS feed – Phase 16D `statusbar` (directive §15 track 16D; OP-10).
2 |
3 | The operator launched the shipped shell and saw the status bar report
4 | " concurrency count unavailable (fail-closed)" (OP-10 first-use finding). Root cause: the
5 | always-visible status bar reads the subscription-concurrency n/2 count over the `subscription_status`
6 | IPC op, but the gateway the running shell actually spawns is the `EchoControlSurface` (diagnostic
7 | transport), which does NOT expose that op – so the read fails and the bar degrades, honestly but
8 | uselessly, to the em-dash unknown. The tested IPC read path (`apps/desktop/statusbar/source.js` +
9 | `apps/desktop/test/statusbar-source.test.js`, proven against a real seeded `SubscriptionGovernor`)
10 | is correct; it simply has no governor-backed surface to talk to in the shipped shell.
11 |
12 | `statusbar` closes that gap the SAME way 16B (picker) and 16C (`selection`/`.spawn`/`.dispatch`)
13 | closed theirs: a bounded one-shot `py -3.12` read-source emitter – NOT the WS-IPC channel – that
14 | builds the REAL `SubscriptionGovernor`, seeds it from the enforced `LiveAuthorization` scope (the
15 | same `config/live_operation.json` gate every live path reads), and prints its `status()` as one JSON
16 | line the shell folds through the pure `terminal/statusbar/statusbar-model` view. The shell renders a
17 | readable `**n/allowance**` count instead of "unavailable".
18 |
19 | SUBSTITUTION (directive §6, recorded): a bounded subprocess emitter, not the authenticated WebSocket
20 | IPC surface (`SubscriptionStatusControlSurface`). The IPC surface stays the design endpoint for a
21 | long-lived governor-backed gateway; wiring it into the shell's gateway process would REPLACE the
22 | `EchoControlSurface` the supervisor's `health`/`session_event` liveness path already rides – a
23 | first-launch regression risk exactly of the class D-P16-0 warns against – so `statusbar` uses the
24 | proven, isolated read-source instead. Recorded here and in the evidence report.
25 |
26 | HONESTY (invariant 3; §6; §10.4). The emitted count is REAL, not fabricated:
27 | * `allowance` is the operator-authorized OP-6 ceiling read from the enforced `LiveAuthorization`
28 |   (governor-capped at 2; a config may narrow, never widen);
29 | * `in_use` is the count of `active` terminals held by the governor this emit builds. The governor
30 |   is built FRESH per emit and is NOT wired to any live-session tracker, so in the non-interactive
31 |   build `in_use` is structurally `*0*` – a truthful, honest zero (the governor WAS read and holds
32 |   no active terminal; the shell drives no live frontier session – mock-first §2.4, live drive is
33 |   operator-run / gate 16F), distinct from the em-dash "we could not read". It only ever UNDERstates
34 |   concurrency (the fail-safe direction – it can never mint capacity or authority).
35 | DYNAMIC per-session tracking – `in_use` rising/falling as the shell itself spawns and reaps live
36 | workers against a SHARED, long-lived governor – is OWED to gate 16F (recorded
37 | `live_session_tracking.owed`), where the shell actually drives live spawns. `statusbar` makes the
38 | authorized ceiling + the current (0) held-count READABLE; it does not yet watch live sessions.
39 |
40 | FAIL-CLOSED (invariant 3 / invariant 20 spirit). `load_live_authorization()` fails closed: absence
41 | of `config/live_operation.json` (a fresh clone) DENIED, and this emits `authorized:false`,
42 | `status:null` – which the JS fold renders as the em-dash unknown with the reason attached, never a
43 | fabricated "0/2". A malformed/out-of-scope config RAISES `LiveAuthorizationError`; the emitter reports
44 | it as `authorized:false, status:null` with the reason, so the bar stays honest rather than crashing.
45 | No model call, no credential, no network (§2.2/§2.4): the emitter only reads the authorization gate
46 | and builds an in-memory governor.
47 |
48 | `--emit-subscription-status` prints ONLY the feed JSON (the stable shell contract, one line).

1 | """Governed WORKER **launch ticket** – Phase 17B `.ticket` (directive $16 track 17B; closes the
2 | authorization half of U70).
3 |
4 | 17A gave pane 1 an executable authorization (`emit_conductor_launch`) and the operator's conductor
5 | went live. A picker selection on any OTHER pane still produced nothing: 16B recorded the choice,
6 | badged it, and stopped at `selected_awaiting_governed_spawn` – the operator's first-use finding F3
7 | ("selecting a model records + badges but launches nothing").
8 |
9 | This emitter is the worker's equivalent of the conductor ticket. ONE picker selection in (on stdin,
10 | verbatim from what the operator was shown), and out comes either
11 |
12 | * an **authorized ticket**: the interactive argv, the RESOLVED binary, the governed workspace, the
13 | NAMES of the credential-bearing env vars the shell must drop ($2.2 – names, never values), the
14 | node identity minted PYTHON-side, the pane chrome, and – for a frontier selection – a **durable
15 | I-X3 lease that is still held**, because the session it authorizes will outlive this emitter; or
16 | * a **fail-closed refusal ticket** (`authorized:false`, `refused:true`, `reason`, no argv, no
17 | lease) for every gate that said no: a greyed option, the conductor role, an unauthorized live
18 | config, unconfirmed R8 $6 terms, an absent CLI, a full durable I-X3 count, an unreadable ledger,
19 | a local model whose VRAM cannot be proven, or a selection this emitter cannot even parse.
20 |
21 | Two localities, two different governors – deliberately, per invariant 19:
22 |
23 | * **frontier** (`claude_code` / `openai_codex_cli`, the OP-6 scope and nothing else) is
24 | subscription-governed: the durable ledger is seeded into this process's `SubscriptionGovernor`
25 | so terminals held by the shell are visible here, the gate chain runs, and the lease is taken for
26 | the SESSION key the shell chose before it asked (U75/U77 – reclaimable even if this ticket never
27 | arrives). The `--model` slug is read OFFLINE from the 17A probe ledger, so a worker asks for the
28 | id the CLI actually accepts rather than the operator's label (the `.roundtrip` defect).
29 | * **local** (`ollama_local`) holds NO subscription terminal and needs NO credential. What governs
30 | it is VRAM residency (invariant 22): the selection routes through the same host planner the
31 | picker's residency chips came from, and a model whose footprint cannot be proven is refused.
32 |
33 | This emitter makes NO live model call and touches no credential: it builds argv, counts terminals and
34 | reserves VRAM. The ConPTY launch is the shell's, under this authorization (`spawn`).
35 |
36 | Modes (a governed refusal is still a 0-exit JSON ticket; usage errors exit 2 with no JSON):
37 | --emit-worker-launch --holder-pid <pid> --session-id <id> --pane-id <pane> (selection on stdin)
38 | --release-session <session_id> hand back the terminal held by one session, any subscription
39 | --release-lease <lease_id> hand one durable terminal back by id

282 |
283 |     **Scoped to the selected provider (validator MAJOR-3).** Until the 18B close this called
284 |     `build_host_picker()` bare, which probes BOTH OP-12 CLIs unconditionally – so selecting a local
285 |     `qwen3:8b` pane, with no subscription and no credential, emitted a metadata request to grok.com
286 |     under the operator's SuperGrok session before the pane opened. D-P18-7 disclosed that cost for
287 |     the PICKER site, where the operator has asked to see every provider; it was never disclosed for
288 |     the launch path, and on a local selection it is not merely undisclosed, it is unowed
289 |     (invariants 19/20 – locality is per node, and an offline-profile pane should not reach the
290 |     network to be verified). A selection that is not for an OP-12 provider now verifies against an
291 |     enumeration built with `no_op12_probes()`: the OP-12 groups render as not-probed, which cannot
292 |     affect the match, because an option's identity carries its own provider.
293 |
294 |     **And the seam is now threaded (validator MAJOR-2).** `op12_probes` is the same host-free seam
295 |     `build_host_picker`/`enumerate_pane_picker.main` already published; it stopped at this caller,
296 |     so a deterministic test that reached `main()` fired a real `grok --version` against the host –
297 |     which `tests/live_call_guard` then refused at `grok models`, turning the one test covering the
298 |     CLI contract into a test of its refusal branch. D-P18-5 claimed the suite never makes these
299 |     calls; it does not now."""

448     """Invariant 20 consulted BEFORE the host enumeration, not only after it (spec-audit F2, U303).
449
450     The air-gap gate proper lives downstream in `worker_pane_spawn.assert_startup`, and it refuses
451     every frontier adapter on an offline profile. But `_assert_option_offered` runs FIRST, and for
452     an OP-12 selection it enumerates through `only_op12_probe(provider)` - `grok models` / `agy
453     models`, which leave the host (D-P18-7/U271). So an air-gapped host emitted provider metadata
454     traffic and THEN refused the pane. The verdict was right and the ordering was not, which for
455     invariant 20 is the whole point: "excluded from the offline profile" has to mean the network was
456     never touched, not that the answer came back no. Closing the parameter default made this
457     reachable at all - before it, the manufactured `cloud` loader meant the gate never fired here.
458
459     Refusing on the CALLER's claimed adapter is sound because it can only refuse MORE: the claim is
460     already what scopes the probe (`_host_offered_options(provider=...)`) , a lie about it cannot
461     produce an authorization (the identity match downstream still has to succeed against the host's
462     own enumeration), and the real gate still runs on the HOST's option for everything that gets
463     past here. `ProfileViolation` is raised rather than a new refusal id because this IS that gate -
464     `_EXCEPTION_GATE` maps it to `profile_roster` either way, so a reader cannot tell the two sites
465     apart, and should not have to."""

1 | """Phase 15E `.picker` – operator-run enumeration driver (Phase-1 spike substitution pattern).
2 |
3 | The per-pane picker's DATA MODEL (`control_plane/nodes/pane_picker.build_pane_picker`) and the
4 | VRAM residency planner (`scheduler/residency_planner`) are pure and covered by the headless
5 | suite. What THIS session cannot verify is the *live host enumeration* that feeds them: the real
6 | `ollama list` result and each running model's real VRAM footprint. This driver is the
7 | operator-run metric that captures those real inputs and prints the exact picker JSON the shell
8 | selector would render – like `tools/spike_compositor` for the Phase-1 window, it is NOT part of
9 | pytest and makes no assertion; it records what the host actually reports.
10 |
11 | It performs NO frontier model call and touches NO credential ($2.2). Frontier availability is read
12 | from the enforced `LiveAuthorization` gate, the `codex` presence/auth probe, and – since 18B
13 | `.picker` – up to four bounded METADATA calls to the OP-12 CLIs (`grok --version`/`models`,
14 | `agy --version`/`models`). Those two are not purely local: `grok models` reaches grok.com to report
15 | the signed-in session (recorded in `probe_op12_providers`). They are token-free, prompt-free and
16 | model-free, and they run whatever the live switch says, because the option set must be the CLI's
17 | own listing rather than a guess (D-P18-7). Local model footprints come from the Ollama daemon's own `/api/ps` (VRAM of
18 | running models) and `/api/tags` (on-disk size as a fallback estimate) – RECORDED as which, never
19 | fabricated. If the daemon is unreachable the local list is empty and that is reported honestly.
20 |
21 | Run (Windows host, operator): py -3.12 tools/live/enumerate_pane_picker.py
22 |     --emit-picker      the picker dict only (the shell's stable contract)
23 |     --emit-residency  the VRAM budget + planner snapshot only (deterministic-arithmetic contract)

222 |     """Why NO local option can be authorized on this host right now – or None, which means only
223 |     that none of the host-wide conditions THIS FUNCTION COVERS refuses them.
224 |
225 |     Deliberately NOT covered, and why (an exhaustive "or None if they can be" would be false –
226 |     validator MINOR-1, round 3):
227 |     * the per-model fit gate (`_assert_fits_without_displacing`) – a model can be too large for
228 |     this host's budget while its neighbours fit, so it is not a fact about the LIST;
229 |     * `role_deferred` – a local CODING pane is the worktree-isolated OpenCode path, so every
230 |     local option is refused for that ROLE while the same options are launchable for
231 |     `reasoning`. The picker offers roles per option, not per list, and greying the whole list
232 |     would be wrong for the role the operator is actually choosing (U95 owns the coding path);
233 |     * `vram_budget_mismatch` – host-wide in principle, but the enumeration produces the planner
234 |     and the budget from one call with one total, so the two cannot disagree on this path; it is
235 |     defence in depth against a future caller, not a state to render.
236 |
237 |     17B turned the residency planner into an authorization gate: with no established budget,
238 |     `worker_pane_spawn._authorize_local` refuses EVERY local selection. Offering them all as
239 |     `available:true` shows the operator something the gate will not honour – the picker's own
240 |     greyed-with-reason contract, never extended to the condition 17B introduced (spec-audit
241 |     MAJOR-2, 2026-07-26).
242 |
243 |     The FIRST fix covered only the budget condition, and the refusal set is wider: the picker's
244 |     model list comes from the daemon over HTTP (`detect.ollama_models`) while the pane needs the
245 |     `ollama` BINARY on PATH (`detect.ollama_executable`) – two independent facts, and
246 |     `worker_pane_spawn`'s own refusal text already said so. A reachable daemon with no launchable
247 |     CLI offered every model as available while the gate refused all of them: the same defect, in a
248 |     second documented state (independent gate-validator MAJOR-A, 2026-07-26). Both host-wide
249 |     conditions are covered here; each names itself, so the operator gets the right fix."""

264 |     """The REAL host's VRAM residency planner + the PROVENANCE of the budget it enforces.
265 |
266 |     Returns `(planner_or_None, budget)` where `budget` is `{vram_budget_mb, budget_source, estimate,
267 |     established, running_vram_mb}`. A `None` planner is always accompanied by `established:false` and a
268 |     `budget_source` naming what broke (daemon unreachable, or a budget the host's own residency
269 |     falsified) – the local authorization gate refuses on it and repeats that reason, so "could not
270 |     establish a budget" is never silently rendered as "does not fit".
271 |
272 |     The budget travels WITH the planner deliberately: 17B turned this planner into

```

```

273 | an authorization gate, and an authorization made against an estimated budget must say so at the
274 | authorization site, not only in this module's provenance rows (gate-validator R2, 2026-07-26).
275 |
276 | Public because the worker launch ticket must route a local selection through the same
277 | ENUMERATION the picker's residency chips came from (invariant 22): a planner built from
278 | different inputs could refuse a model the operator was shown as loadable, or accept one it was
279 | not. HONEST PRECISION (spec-audit MINOR-13): it is the same BUILDER, not the same planner
280 | object or the same observation – the ticket path queries the daemon again, so a model that
281 | became resident between the two reads is seen by the second and not the first. What the rule
282 | buys is that both reads apply identical arithmetic to whatever the daemon reports; a live
283 | daemon is not a snapshot and this module cannot make it one.
284 |
285 | HONEST LIMITS (U96): (a) this planner is in-process and dies with the emitter, so a reservation
286 | it makes is not durable the way a terminal LEASE is – the authoritative VRAM allocator on the
287 | host is the Ollama daemon itself; (b) unless `SOW_VRAM_BUDGET_MB` is set, the budget is a
288 | stand-in CONSTANT, never a GPU query – so on a card larger than the stand-in the operator may be
289 | refused a pane that would really fit, and on a smaller one admitted to one that would not. What
290 | the rule guarantees is only that the budget is never derived from the resident set. What it
291 | enforces is a fail-closed ADMISSION rule (an unsized
292 | or over-budget model is refused, and the worker path additionally refuses anything that would
293 | only fit by displacing a model the daemon is already serving) plus the visible residency STATE
294 | – not cross-process arbitration.""

9 | **This is not TTS in the product sense, and it is deliberately kept where it cannot become that.**
10 | I-V2 / D-VOICE-02 prohibit the SYSTEM speaking back to the operator; the frozen invariant is about the
11 | product's voice OUTPUT surface. This tool synthesizes a transcription INPUT for a test, lives in
12 | `tools/` rather than in a product tree (`apps/`, `adapters/`, `voice_bridge/`, `control_plane/`), and
13 | plays nothing to any speaker – it writes a file. It is not, however, *unreachable* from the product:
14 | the packaged Electron main requires the self-checks, which SPAWN this script under `SHELL_SELFCHECK`
15 | (see the correction below – that reachability is the honest fact, and the file-only sink is what
16 | actually enforces I-V2). The identical carve-out was made and recorded at Phase 16E
17 | `.real` (`tools/live/real_parakeet_smoke.py`, receipt `PHASE16E_REAL_PARAKEET_SMOKE.json`: *OS
18 | System.Speech (test input only; NOT product TTS)*); this is the same precedent, restated rather than
19 | assumed.
20 |
21 | **One clause of that argument went stale and is corrected here (Phase 17C `.close`, spec-audit
22 | MINOR-8).** It used to say this tool "is imported by no shipped module". Since `.mic` and `.close` the
23 | in-Electron self-checks SPAWN it, and those modules are `require`d unconditionally by the packaged
24 | Electron main process – so the shipped app does contain a code path that reaches `System.Speech`. It is
25 | reachable only under `SHELL_SELFCHECK`, and the self-checks now assert that themselves rather than
26 | relying on nobody calling them by accident. The substantive guarantee is unchanged and is enforced
27 | below by construction: the synthesizer's only sink is a file, verified present before `Speak` is
28 | called at all.
29 |
30 | Prints one JSON line describing what it wrote (or why it could not) and exits 0/1. Local processes
31 | only (`powershell.exe`); no network, no credential, no model call (directive §2.2/§2.4).

1 | """Governed live PROBE of the conductor's `--model` slug - Phase 17A `.roundtrip`.
2 |
3 | `emit_conductor_launch` must stay offline: the shell requests its ticket on a bounded timeout and a
4 | launch path that makes a live call inside it is a launch path that hangs. So the live half lives
5 | here, in its own bounded tool, and the ticket emitter only READS what this recorded.
6 |
7 | What it does, in order, refusing rather than improvising at every step:
8 |
9 | 1. the SAME live-gate chain the conductor launch runs - live-operation switch -> provider-live ->
10 |    R8 $6 operator terms (OP-9) -> `claude` present on the host;
11 | 2. takes ONE durable I-X3 terminal for the duration of the probe, owned by THIS process, and hands
12 |    it back in a `finally` (D-LOOP-1: nothing this tool spends outlives it). Both terminals already
13 |    in use a governed refusal, not a third session;
14 | 3. runs `probe_claude_model` - at most one minimal live call per candidate slug, stopping at the
15 |    first acceptance;
16 | 4. writes the result to the host-local probe ledger so the next launch is offline and instant.
17 |
18 | A conclusive record already in the ledger short-circuits the whole thing (no gate mutation, no live
19 | call) unless `--reprobe` is passed - the operator's lever for "the CLI changed, ask again".
20 |
21 | Modes (a governed refusal is still a 0-exit JSON payload; usage errors exit 2 with no JSON):
22 | --emit-model-probe [--label <label>] [--reprobe] [--ledger-only]

1  """Reproducible on-host evidence: the real `WslParakeetSTT` adapter transcribes real speech via
2  WSL2 -> NeMo -> GPU (Phase 16E `.real`; directive $15 track 16E; OP-10; OP-9/$10.3 authorizes the NeMo
3  stack). Run on the Windows host after the operator install (docs/OPERATOR_NEMO_INSTALL.md):
4
5      py -3.12 tools/live/real_parakeet_smoke.py
6
7  It (1) generates a short WAV with the OS speech synthesizer as a TEST-INPUT FIXTURE ONLY – this is a
8  transcription input generator, NOT a product feature; the PRODUCT never synthesizes speech and exposes
9  no speak/TTS method (frozen invariant I-V2 / D-VOICE-02), and this tool lives outside the product voice
10 path (adapters/apps) – then (2) transcribes it with the REAL shipped adapter and writes a machine-
11 readable receipt. Skips-with-record (exit 0, ok:false, reason) when the real stack is absent, so it is
12 safe on any host. Spawns only local processes (`powershell.exe` for the fixture, `wsl.exe` for NeMo);
13 no `claude`/`codex`, no credential, no network (directive $2.2/$2.4). transcribe-then-discard: the
14 fixture WAV is deleted on the way out (invariant 26)."""

41     its caller keys off `wav.exists()` rather than the shell's exit code (spec-audit m-B).
42     The previous body ran under PowerShell's default
43     ``$ErrorActionPreference = 'Continue'``: a throwing ``SetOutputToWaveFile`` is NON-terminating,
44     so ``Speak`` would then have rendered the phrase to the host's DEFAULT AUDIO DEVICE. Nothing
45     shipped reaches this script -- it is an operator-run diagnostic in ``tools/`` -- so I-V2 /
46     D-VOICE-02 were never at risk in the product. But a latent path from this repo to a loudspeaker
47     is not something to leave lying next to an invariant that says the system never speaks.
48
49     Now: errors are terminating, the sink is asserted to be the file BEFORE ``Speak`` is called, and
50     any failure is a non-zero exit rather than an audible one.
51     """

1  """Phase 15D `.debate` LIVE re-run – operator-run live smoke (OP-9, directive §14).
2
3  This is NOT part of `pytest tests/`: it spawns the REAL host `claude` CLI for every debater,
4  which the deterministic suite must never do (`tests/integration/test_live_debate_flow.py` proves
5  the identical governed path MOCK-FIRST – no process). This is the live analogue of the Phase-1
6  spike's operator-run metric: ONE bounded debate through the SAME Phase-7-gated Debate Service and
7  the SAME live-spawn gates the mock-first suite exercises
8  (`control_plane.orchestration.live_debate.attempt_live_debate`), but with genuine
9  `ClaudeCliBackend` debaters, so each leg can be recorded `live` when – and only when – the CLI
10 reports back a verified executing checkpoint for a call spent inside THIS debate.
11
12 Directive §11 15D: "one bounded live debate (budgets enforced – real tokens now)". Everything the
13 governed path enforces still applies here and is un-bypassable by this driver:
14 - ≤5 rounds hard cap, per-debate budget + per-caller quota + global concurrent cap (invariants
15   14/17); a clean budget-exhaustion cutoff; dissent preserved VERBATIM (invariant 15);
16 - two DISTINCT live backends (invariant 18 – no node solely judges its own work); the caller is
17   a NON-conductor node (§2.8 – the service is not conductor-coupled);
18 - every live gate in `spawn_claude_code_terminal` (profile+live auth, provider gate re-asserted,
19   R8 §6 operator terms, CLI presence, I-X3 concurrency ≤ authorized allowance).
20
21 OP-9 discharged the R8 §6 [OPERATOR] live-terms gate for `claude_code`; this driver passes
22 `operator_terms_confirmed=True` on that RECORDED basis (invariant 1: the loop did not make that
23 determination, the operator did). Any OTHER unmet gate  skip-with-record, NO live call (§10.4).
24
25 Honesty (§6/§10.4): the outcome is reported EXACTLY as the governed path records it.
26 `build_debate_report` refuses to package any leg as `live` without a VERIFIED checkpoint for that
27 debater, so a mock/attempted/skipped leg can never be dressed up as a real-provider result.
28 D-LOOP-1: `attempt_live_debate` spawns → exercises → tears down within the call (synchronous
29 `subprocess.run` with a hard timeout per `generate`, and every I-X3 terminal released in a
30 `finally`), so no live process outlives this driver.
31
32 Usage:  py -3.12 tools/live/run_15d_debate_live_smoke.py [--model SLUG] [--max-rounds N]
33         [--timeout SECONDS]
34
35 By default each debater requests the CLI DEFAULT model (no `--model`), which is the most reliable
36 way to obtain a verified live checkpoint on an arbitrary host (the fable-5 slug acceptance was
37 confirmed end-to-end at `.flow`, U33). Pass `--model claude-fable-5` to drive the debaters on the
38 conductor selection's own checkpoint.

1  """Phase 15D `.flow` LIVE re-run – operator-run live smoke (OP-9, directive §14).
2
3  This is NOT part of `pytest tests/`: it spawns the REAL host `claude` CLI, which the
4  deterministic suite must never do. It is the live analogue of the Phase-1 spike's
5  operator-run metric – one governed run through the SAME gated path the mock-first suite
6  proves (`control_plane.orchestration.live_flow.attempt_live_flow`), but with a genuine
7  `ClaudeCliBackend`, so the conductor leg can be recorded `live` when – and only when – the
8  CLI reports back a verified executing checkpoint.
9
10 OP-9 discharged the R8 §6 [OPERATOR] live-terms gate for `claude_code`; this driver passes
11 `operator_terms_confirmed=True` on that recorded basis (invariant 1: the loop did not make
12 that determination, the operator did). Every OTHER gate still applies: the real repo
13 `config/live_operation.json` must authorize `claude_code`, the CLI must be present, the
14 subscription governor caps at the authorized allowance. Any unmet gate  skip-with-record,
15 no live call (directive §10.4).
16
17 Honesty (directive §6/§10.4): the outcome is reported EXACTLY as the governed path records
18 it. A run that reached the model but returned no verifiable checkpoint degrades to
19 `attempted`; a mock or skipped leg is never dressed up as `live`. `build_acceptance_packet`
20 enforces this by construction. D-LOOP-1: `attempt_live_flow` spawns → exercises → tears
21 down within the call. The CLI runs in a managed process tree: every assigned PID is tracked,
22 the complete tree is terminated and awaited in `finally`, and a surviving descendant fails
23 the run rather than being left for the loop to discover.
24
25 Usage:  py -3.12 tools/live/run_15d_flow_live_smoke.py [--model SLUG] [--timeout SECONDS]
26
27 The conductor SELECTION stays fable-5 (operator-selected, invariant 3) regardless of which
28 checkpoint actually executes; the executing checkpoint is recorded separately and honestly.
29 By default the smoke requests the CLI default model (no `--model`), which is the most
30 reliable way to obtain a verified live checkpoint on an arbitrary host; the exact `fable-5`
31 slug acceptance is a separate probe (U33). Pass `--model claude-fable-5` to attempt the
32 selection's own checkpoint directly.

1 | """Phase 15D `.succession` LIVE re-run – operator-run live smoke (OP-9, directive §14).
2 |
3 | This is NOT part of `pytest tests/`: it spawns the REAL host `claude` CLI for the predecessor
4 | conductor's decomposition, which the deterministic suite must never do
5 | (`tests/integration/test_live_succession.py` proves the identical governed handover MOCK-FIRST –
6 | no process, pinned by a `subprocess.Popen` ban). It is the live analogue of the Phase-1 spike's
7 | operator-run metric: ONE governed conductor succession through the SAME gated path the mock-first
8 | suite exercises (`control_plane.orchestration.live_succession.LiveConductorSuccession`), but with a
9 | genuine live claude_code conductor as the PREDECESSOR – so the conductor that gets killed is a real,
10 | subscription-spending Fable-5 conductor with a VERIFIED executing checkpoint, not a mock.
11 |
12 | Directive §11 15D / OP-9 §2: "kill the live Fable-5 conductor mid-run, resume on a different
13 | live/local backend, zero project loss, restore selection." Everything the governed path enforces
14 | still applies here and is un-bypassable by this driver:
15 | - the KILL is real: the predecessor's adapter is closed (releasing its subscription terminal) and
16 |   its MCP session ends; if it survives `close()` the succession is REFUSED, never reported;
17 | - the successor is a SEPARATELY-CONSTRUCTED adapter on its OWN MCP session + node id that reloads
18 |   all 12 conductor files FROM shared memory (invariant 5), gated by the §19.1 staleness checklist;
19 | - ZERO LOSS is compared by CONTENT HASH read back from MCP, never by entry id, never by trusting
20 |   a node's own `content_hash` (I-M1);
21 | - the succession report is published CANDIDATE by the successor and promoted by a SEPARATE gate
22 |   node (invariant 18), `operator_disposition: pending` (invariant 1);
23 | - I-X3 release-before-acquire is OBSERVED on the real `SubscriptionGovernor`.
24 |
25 | WHY THE PREDECESSOR IS THE LIVE LEG, AND THE SUCCESSOR IS NOT. `LiveGovernedFlow._synthesize`
26 | assembles the acceptance packet DETERMINISTICALLY from MCP reads + gate records – it never calls
27 | the successor's backend (U46/U58). So a successor conducts (loads its 12 files, reads the ACCEPTED
28 | set, publishes, is gated) WITHOUT spending a model call, and the leg vocabulary – which reports
29 | model SPEND, not activity – records its leg `skipped` regardless of which backend it is. The
30 | meaningful LIVE element of a succession is therefore the KILLED conductor: its live decomposition
31 | call is a genuine Fable-5 subscription spend. This driver makes the predecessor a real
32 | `ClaudeCliBackend` and keeps the successor a distinct mock backend (`mock-successor`), exactly as
33 | the mock-first suite records the successor leg – fully honest, and no extra live call spent.
34 |
35 | OP-9 discharged the R8 §6 [OPERATOR] live-terms gate for `claude_code`; the predecessor factory
36 | passes `operator_terms_confirmed=True` on that RECORDED basis (invariant 1: the loop did not make
37 | that determination, the operator did). An unauthorized/absent `live_auth` still raises through
38 | `spawn_claude_code_conductor`'s ordered gates (assert_startup + assert_provider_live) and becomes a
39 | skip-with-record with NO live call (§10.4). NOTE: because this driver INJECTS a real backend, the
40 | spawn's own CLI-presence gate is bypassed (`conductor_spawn` skips it whenever a backend is supplied),
41 | so the detected `cli_present` value passed here is inert; an absent `claude` binary instead fails
42 | closed one layer down – `ClaudeCliBackend.generate` raises `FileNotFoundError` → `ClaudeCodeAuthError`,
43 | caught by `LiveConductorSuccession.run()` and reported as a skip-with-record, still with no spend and
44 | no naked session.
45 |
46 | Honesty (§6/§10.4): the outcome is reported EXACTLY as the governed path records it. The
47 | predecessor leg is `live` only when the CLI reported back a VERIFIED executing checkpoint for a call
48 | spent inside THIS run; `zero_loss.ok` is preservation (nothing lost) and `work_advanced` is the
49 | anti-vacuity strengthener (the successor completed work the predecessor never saw). With a
50 | dependency-free live decomposition the whole graph finishes in one wave, so `work_advanced` can be
51 | False even though the kill + governed handover + zero-loss preservation all held – that is recorded,
52 | never dressed up. D-LOOP-1: the only live child is the predecessor's synchronous `subprocess.run`
53 | decomposition (hard timeout), and `LiveConductorSuccession.run()` tears every adapter/client down in
54 | a `finally`, so no live process outlives this driver.
55 |
56 | Usage: py -3.12 tools/live/run_15d_succession_live_smoke.py [--model SLUG] [--timeout SECONDS]
57 |         [--kill-after-waves N]
58 |
59 | By default the predecessor requests the CLI DEFAULT model (no `--model`), the most reliable way to
60 | obtain a verified live checkpoint on an arbitrary host (the fable-5 slug acceptance was confirmed
61 | end-to-end at `.flow`, U33). The conductor SELECTION stays fable-5 (operator-selected, invariant 3)
62 | regardless of which checkpoint actually executes; the executing checkpoint is recorded separately
63 | and honestly. Pass `--model claude-fable-5` to drive the predecessor on the selection's own slug.

33 | @"
34 | You are the autonomous builder for this repository. Read AUTONOMOUS_BUILD_DIRECTIVE.md
35 | (all sections, including s9 Phase 14 and s10 operator authorization OP-4/OP-5) and
36 | docs/loop/LOOP_STATE.json now, then execute the Loop Protocol (directive section 3)
37 | for EXACTLY ONE work unit. Reconcile state to git tags first if they disagree. Implement
38 | test-first, self-check every exit criterion with real command output, run the
39 | gate-validator subagent for confirmation (mandatory for high-stakes gates incl. 14A),
40 | write the evidence report, follow the two-commit convention, tag passed gates, update
41 | docs/loop/LOOP_STATE.json (increment iteration; set consecutive_failures correctly;
42 | set status COMPLETE or BLOCKED only per directive section 8), commit the state change,
43 | and exit. Do not ask the operator anything. Do not exceed one work unit.
44 |
45 | PRINT-MODE FACT (D-LOOP-2, binding): you are running under 'claude -p'. Your process
46 | ENDS when your turn ends. Background tasks (subagent reviews, test suites, waiters,
47 | heartbeats) DO NOT survive your turn, and NO completion notification will EVER re-invoke
48 | you - 'waiting for notifications' is waiting for something that cannot happen and trips
49 | the stall guard. Therefore: run the gate-validator, spec-auditor, and any test suite IN
50 | THE FOREGROUND and wait for them synchronously INSIDE this turn. Never end a turn
51 | 'waiting' or 'standing by'. If LOOP_STATE or an evidence draft claims reviews/suites are
52 | 'in flight' from a prior iteration, they are DEAD - re-run them fresh, foreground. If a
53 | unit cannot fit its reviews in one turn, split it: commit an explicit work-in-progress
54 | checkpoint (so the stall guard sees progress) with LOOP_STATE recording exactly what
55 | remains, then complete reviews+finalization as the next unit's first act. If you spawn
56 | ANY child process, watcher, or monitor this turn, poll it to completion (or kill it,
57 | D-LOOP-1) BEFORE the turn ends - in-turn polling is the ONLY mechanism that exists;
58 | 'waiting for the monitor notification rather than polling' is choosing a channel that
59 | does not exist and has already killed one iteration (16d.recovery, 2026-07-24).

1  """Mutation runner for the guards added at the Phase 188 `.close` gate.
2
3  Kept in the tree rather than run once and described, because a mutation result asserted in a
4  report is exactly the class of claim this track has been reopened over three times: prose that
5  cannot disagree with its value. Run it and the eight verdicts are reproduced.
6
7  Each entry: (path, old_bytes, new_bytes, selector). It applies the mutation, runs the selector,
8  records RED (a test caught it) or GREEN (nothing did), restores the original bytes, and verifies
9  the restore is BYTE-IDENTICAL by sha256. Exit 1 if anything is GREEN or a restore diverges.
10
11  What it covers, and why each one exists:
12  * the three $14 display-label surfaces – the operator directive's one verbatim label prohibition
13    ('do not display `Gemini CLI` for the Google AI Pro path'), which at the close review could be
14    violated with the whole 1870-test suite green (validator BLOCKING-1);
15  * `registered_providers()`'s U256 spawnability intersection, deletable with the suite green
16    (validator MEDIUM-1);
17  * the status bar's display-ceiling clamp (spec-audit MINOR-1 / U277);
18  * the three halves of the launch-path enumeration scoping – the rule, the provider set (the
19    WRONG entry, not the missing one: U275), and the seam's threading through the product path
20    (validator MAJOR-2 / MAJOR-3).
21

1  """Mutation runner for Phase 19 unit 1 – the OP-13 revert of the provider permission-mode widening.
2
3  Same contract as its siblings: apply one mutation, run one selector, record RED (a test caught it)
4  or GREEN (nothing did), restore the original bytes, verify the restore is BYTE-IDENTICAL by sha256.
5  Exit 1 if anything is GREEN or a restore diverges.
6
7  Most rows below RESTORE A SHIPPED BEHAVIOUR: the `new` string is the code that was on the tree at
8  `b109f02`, the last of the seven untagged post-18E commits. Four are not byte-exact restorations and
9  each says so at its own entry, because a blanket provenance claim would be the inference-stated-as-
10 evidence this unit exists to correct (gate-validator round-2 MEDIUM-2, spec-audit MINOR-4): **M2** is
11 signature-only and produces a state that was never shipped; **M7/M8** are single-factor mutations of
12 the CURRENT line (isolating one flag each) rather than the shipped line that moved two; **M9/M10**
13 inline literals or re-flow prose because the constants and the line structure they used are gone.
14 Each still reproduces the DEFECT it names. That is the point of this harness. The
15 operator's ruling (OP-13) is that Antigravity's own `accept-edits` mode is not operator approval,
16 and the requirement attached to it is a test that refuses `accept-edits` **for every execution
17 profile, so the carve-out cannot reappear untested**. A revert with no falsification is a diff;
18 these rows are what make it a guard.
19
20 * M1 the `execution_profile` carve-out returns whole – the parameter and the
21 `antigravity_execution` exemption – and `agy --mode accept-edits` is emitted again by any
22 caller that passes the keyword;
23 * M2 the parameter comes back ALONE, defaulted to None, with the guard still unconditional. This
24 row is signature-only and says so: no behaviour changes, and it exists because a keyword a
25 caller can pass is the re-arming surface, which is why the revert deleted it rather than
26 defaulting it off;
27 * M3 `ANTIGRAVITY_HEADLESS_MODE` goes back to `accept-edits` – the exact line OP-13 names
28 (`adapters/frontier/antigravity.py:72`). With the guard unconditional this must fail LOUDLY
29 at the adapter, not quietly at a comment;
30 * M4 the 18A probe's `ANTIGRAVITY_PROBE_MODE` goes back to `accept-edits`, which is the same
31 widening on the diagnostic path the operator runs by hand;
32 * M5 `GROK_HEADLESS_PERMISSION_MODE` goes back to `default` (U327's half of the finding);
33 * M6 `--no-plan` is emitted again beside the restored `plan` pin – the widening under a second
34 name, since the installed capture defines that flag as "Disable plan mode";
35 * M7 `--no-plan` is removed from `FORBIDDEN_PROVIDER_ARGS` again, so nothing refuses it even
36 though no builder emits it. M6 is the emission; M7 is the policy. A revert that fixed only
37 one of them would leave the other free to bring the widening back.
38
39 Rows M8-M11 were added after the mandatory reviewers ran on the first version of this unit and each
40 found residue the revert had missed (gate-validator MAJOR-1, spec-audit MAJOR-1/2/3/4, MEDIUM-6):
41
42 * M8 `--allow` leaves the forbidden list again (U340, the policy half);
43 * M9 the interactive Grok builder emits `--allow mcp__sovereign__` again (the emission half –
44 it is a separate row because with M8 unapplied the builder refuses its own argv, which is
45 the fail-closed behaviour this unit restored and wants proven);
46 * M10 the Antigravity launch note goes back to the hand-written `--mode accept-edits` prose. This
47 is the row that did not exist when the reviewers found the defect: the argv was reverted and
48 the ticket still ADVERTISED the forbidden mode, invisibly to 2262 tests;
49 * M11 `.grok/config.toml` supplies `permission_mode = "default"` again – the repo's own tracked
50 config handing a node-controlled default to the pin that exists to refuse one.
51
52 Note on numbering: the `MUTATIONS` list carries an M1b row (the carve-out's second half) so the
53 count printed at the end is one higher than the highest label.
54

1 | """Mutation runner for Phase 18C `.close` – the OP-12 acceptance verdict rules and the one
2 | operator-facing instruction this unit corrected.
3 |
4 | Same contract as `_op18c_probe_path_mutations.py`: apply the mutation, run the selector, record RED
5 | (a test caught it) / GREEN (nothing did) / SETUP-FAIL (the run did not happen), restore the original
6 | bytes, verify the restore is BYTE-IDENTICAL by sha256. Exit 1 if anything is GREEN or a restore
7 | diverges. It is in the tree for the same reason: a mutation result asserted in a report is prose
8 | that cannot disagree with its value.
9 |
10 | What each mutation is about – every one of them is a way a GREEN 18C receipt could be produced by
11 | the wrong world:
12 |
13 | 1. **the world check inverted**: a host whose operator HAS opened the switch is read as
14 | fail-closed, so this receipt would stand in for the live legs it exists to say are owed;
15 | 2. **an unreadable authorization read as fail-closed** – "we could not tell" recorded as
16 | "we checked";
17 | 3. **the gate id stops being read**: any refusal, from any gate, accepted as evidence about the
18 | operator's switch (the `_gate_id` lesson: prose can be borrowed, an id cannot);
19 | 4. **`selection_offered` no longer required**: a refusal at the host-enumeration gate – i.e. the
20 | option was never the host's – accepted as the live gate's;
21 | 5. **`cli_present` no longer required**: an absent CLI refuses identically on an authorized host,
22 | so the receipt would prove nothing about the switch;
23 | 6. **the two producers no longer have to agree** about which gate refused;
24 | 7. **a refusal that took a lease** accepted as fail-closed;
25 | 8. **the session count no longer compared**: a refusal that started something passes;
26 | 9. **$14 crossed-provider text** no longer refused;
27 | 10. **an absent ledger entry treated as unknown-but-fine** – the leg's whole point is that
28 | unknown fails closed;
29 | 11. **the painted status-bar text no longer read**: "visible" degraded to "computed" (invariant 27);
30 | 12. **a credential scan with nothing to look for** scored as clean;
31 | 13. **an unread log sink** scored as clean;
32 | 14. **the OWED block no longer required to cite anything** a reader can look up;
33 | 15. **the corrected operator instruction reverted** to the sentence that stopped being true when
34 | 18B `.scope` shipped the code-pinned extension (U289).
35 |
36 | **Scoring, and the Node half of it.** Python selectors are classified by pytest's exit code
37 | (0 GREEN, 1 RED, anything else SETUP-FAIL). Node selectors CANNOT be, and this is the 18B `.close`
38 | lesson made permanent: `node --test` exits non-zero for reasons that are not a failing test at all
39 | (a module resolution error under Node 24 exits 1 with MODULE_NOT_FOUND), which reads as RED for a
40 | mutation nothing guarded. So a Node run is RED only when the TAP summary reports at least one
41 | failure, and any other non-zero outcome is SETUP-FAIL.
42 |
43 | Usage: `py -3.12 tools/mutation/_op18c_close_mutations.py`

```

```

137
138 #: pytest's own exit codes. 0 = all passed, 1 = tests failed. Everything else (2 interrupted,
139 #: 3 internal error, 4 usage error, 5 no tests collected) means the RUN did not happen – which is
140 #: never evidence that a mutation was caught.
141 _PYTEST_ALL_PASSED = 0
142 _PYTEST_TESTS_FAILED = 1
143
144 #: `node --test`'s TAP summary. A Node run counts as RED only if it reports a failing TEST; every
145 #: other non-zero outcome (a module that would not resolve, a syntax error before the runner starts)
146 #: is the harness's own breakage and must never be scored as safety.
147 #: The summary line's MARKER is the reporter's choice and is not even stable through this pipe:
148 #: `node --test` writes `# fail N` under the tap reporter and `fail N` under the spec reporter
149 #: it picks here, and that marker arrives mangled unless the pipe is decoded as UTF-8 (it is, below).
150 #: So the marker is SKIPPED and the COUNT is what is read. Two earlier spellings both scored every
151 #: Node run SETUP-FAIL – failing safe, and reporting nothing: `[# ]` (the character does not
152 #: survive the default decode) and `\\W{0,4}` ( `\\W` is not a word character in Python, so it is a WORD
153 #: character and `\\W` never matches it – a rule that looked right and was empirically false).

1 | """Mutation runner for the governed probe path added at Phase 18C `.probe-path` (U234).
2 |
3 | Same contract as `_op12_close_mutations.py`, and kept in the tree for the same reason: a mutation
4 | result asserted in a report is prose that cannot disagree with its value. Run it and the verdicts
5 | are reproduced.
6 |
7 | Each entry: (path, old_bytes, new_bytes, selector). It applies the mutation, runs the selector,
8 | records RED (a test caught it) or GREEN (nothing did), restores the original bytes, and verifies the
9 | restore is BYTE-IDENTICAL by sha256. Exit 1 if anything is GREEN or a restore diverges.
10 |
11 | What each mutation is about:
12 | 1. **the U75-class defect this unit's own test found before the reviewers did** – counting the
13 |    governor by node id instead of lease key made a SECOND concurrent probe of one provider an
14 |    idempotent re-acquire: it ran uncounted and then released a lease the first probe still held;
15 | 2. the durable lease never released the probe leaks the operator's single terminal (D-LOOP-1);
16 | 3. the in-process governor never released;
17 | 4. the R8 §6 operator-terms gate removed (invariant 1: not ours to assume);
18 | 5. the CLI-presence gate downgraded to "resolve whatever answers to that name" (fail-open);
19 | 6. the env scrub emptied `XAI_API_KEY` reaches the child (§13/§2.2);
20 | 7. the child's workspace binding dropped (`cwd=None` – "wherever we happened to start");
21 | 8. `run_probe` bypassing the session entirely, which is the whole of U234 in one line;
22 | 9. the unreachable-supervisor branch DOWNGRADING to the naked spawn instead of refusing;
23 | 10. `_SUPERVISED_PROBE_PATH` pointing at a module that does not exist (the flag is a CLAIM).
24 |
25 | Added at the 18C review round, each one a GREEN a reviewer found – the mutations that mattered most
26 | were the ones this file did not have:
27 | 11. **`run_probe` selecting the naked `subprocess_runner` instead of the supervised one.** The
28 |    single production line that discharges U234 could be swapped for the exact spawn it forbids
29 |    with the whole suite green, because every test passed `runner=` and nothing ever exercised the
30 |    `runner is None` wiring;
31 | 12. the host deployment profile not reaching gate 1 (an air-gapped host opening a leased session);
32 | 13. the OPERATOR's R8 §6 determination assumed rather than passed (invariant 1);
33 | 14. the child's argv[0] not bound to the executable the gate resolved;
34 | 15. `process_tree_clean` asserted `True` instead of measured from the boundary's own outcome.
35 |
36 | **Scoring.** `run()` classifies by pytest's exit code: 0 GREEN (nothing caught it), 1 RED (a test
37 | failed, i.e. guarded), and ANY OTHER code SETUP-FAIL. The third case is the one this file used to
38 | get wrong: it scored `return code != 0` as RED, so a mutation that produced a SyntaxError (exit 2) or
39 | selected no tests at all (exit 5) was recorded as "a test caught it" – a harness that reports its own
40 | breakage as evidence of safety.
41 |
42 | Usage: `py -3.12 tools/mutation/_op18c_probe_path_mutations.py`

1  """Mutation runner for the guards added while closing the Phase 18D amendment reviews.
2
3  Kept in the tree rather than run once and described, for the same reason as its siblings: a
4  mutation verdict asserted in a report is prose that cannot disagree with its value. Run it and the
5  nine verdicts reproduce. Each entry applies the mutation, runs one selector, records RED (a test
6  caught it) or GREEN (nothing did), restores the original bytes and verifies the restore is
7  BYTE-IDENTICAL by sha256; exit 1 if anything is GREEN or a restore diverges.
8
9  What it covers, and why each exists – every one is a finding from the two mandatory reviewers on
10 the amendment commit `c40c1e3`:
11
12 * M1/M7 the vocabulary fence's two remaining soft spots: a hand-written enum literal in
13   `registry.py` (the check now reads the PARSED source and covers all eleven members, not the
14   four that happened never to appear in prose – validator MINOR-4) and a repopulated
15   `ADAPTER_EXEMPTIONS`, the one path that widens the node vocabulary with no operator ruling and
16   no manifest trace (spec-audit m-7);
17 * M2 the U293 ordering fix reverted at a call site that had no red-able test – it was fixed at
18   three sites and pinned at one, and the other two only misbehave on a platform whose case
19   ordering differs (validator MINOR-1);
20 * M3/M4/M6 the amendment ATTRIBUTION, which was asserted and never authenticated: an invented
21   ruling id, the authentication removed entirely, and a recorded amendment silently re-labelled
22   under a different ruling (spec-audit M-3/m-5);
23 * M5 the two integrity hashes the manifest publishes, both previously falsifiable with `--check`
24   staying green (validator NIT-1 / spec-audit m-4);
25 * M8 a live surface describing U227 as still operator-reserved after OP-12.1 ruled it – the
26   MAJOR-1 class, seven stale sites the work commit's "all nine places" claim had missed;
27 * M9 the SHIPPED OWED block claiming a leg was performed, which passed all three suites because
28   every test asserted against a synthetic fixture (validator MEDIUM-3).
29

7 |
8 | `.amendment` opened the node vocabulary and wired nothing to it. `.close` is the wiring, so the
9 | mutations here are aimed at the claims the wiring makes:
10 |
11 | * C1 the record is written under the SUCCESSOR schema. Declaring `node@1.0` instead must fail –
12 |   the frozen enum has no member for these providers, so a record that claimed it would be
13 |   invalid, and a validator that let it through would be validating nothing;
14 | * C2 the schema validation is REAL. Removing the `validate_node_record` call must fail, or the
15 |   "validates against node@1.1" claim rests on the builder agreeing with itself;
16 | * C3 supervision is READ from the session, never asserted for it (I-C1);
17 | * C4 the record is CLOSED when the session ends – a one-shot probe leaving a node reading
18 |   SPAWNING forever is a D-LOOP-1 leak in the one place an auditor would look for it;
19 | * C5 the registration failure is FATAL to the session. Swallowing it would leave a leased,
20 |   supervised terminal with no node record – the naked-but-leased session the whole chain
21 |   exists to prevent;
22 | * C6 `registrar` stays a required keyword: a default is this module deciding whether the session
23 |   it opens is a Sovereign node;
24 | * C7 the log stays LAZY. An eager registrar wrote an empty `node_events.jsonl` into the
25 |   operator's durable store for every probe refused at gate 1 (found by looking at
26 |   `.sovereign_store/` after a suite run, not by a test – now it is a test);
27 | * C8 the product call site really passes a registrar – a probe engine that quietly stopped
28 |   would leave the wiring true only in the tests that inject one;
29 | * C9 the record uuid derives from the INCARNATION as well as the lease key, or two rows of one
30 |   append-only log carry the same `node_id`;
31 | * C10 the emitter's `ok` cannot go green on an unregistered provider;
32 | * C11 the receipt's verdict cannot go green when the operator's switch has been OPENED – the
33 |   rule that stops this fail-closed receipt ever standing in for the live legs;
34 | * C12 the receipt's OWED block cannot claim the durable-record leg was performed (the U296 shape,
35 |   which is exactly the defect the `.amendment` gate found in the 18C receipt).

1  """Mutation runner for Phase 18E `live.electron.wiring` – the supervised worker PANE as a
2  registered Sovereign node.
3
4  Same contract as its siblings: apply one mutation, run one selector, record RED (a test caught it)
5  or GREEN (nothing did), restore the original bytes, verify the restore is BYTE-IDENTICAL by sha256.
6  Exit 1 if anything is GREEN or a restore diverges.
7
8  Unlike `_op18e_hardening_mutations.py`, almost nothing here RESTORES a shipped behaviour – this
9  sub-step added the wiring, so most rows delete or weaken something that did not exist before. That
10 makes the harness more important, not less: a guard added in the same commit as the code it guards
11 is exactly the guard nobody has watched fail.
12
13 Rows M11, M12 and M22 mutate JAVASCRIPT and run `node --test`, because the shell is where three of
14 the rules live and a Python-only harness would have left them unmeasured (the mistake the `main.js`
15 rules of 17B were found by, spec-audit MAJOR-2).
16
17 M13-M22 are the REMEDIATION rows: one per finding the gate-validator and the spec-auditor returned
18 on the first cut of this sub-step. They matter more than M1-M12, because a guard written in
19 response to a review is a guard whose only evidence of working is the review that asked for it.
20
21 * M1 `registrar` becomes a defaulted keyword again – whether a governed session becomes a
22 Sovereign node answered by this module for every caller (U283/U292(a)'s shape, third time);
23 * M2 `ProviderNodeRegistrationRefused` leaves the governance-refusal tuple, so a registrar
24 refusal escapes as a traceback instead of refusing the SESSION – and the durable terminal
25 acquired moments earlier is never handed back (18D `close`'s rule, inverted);
26 * M3 the ticket stops closing the registrar, so the node log's cross-process lock survives the
27 emitter and the shell's own next call (the attestation) is refused `node_log_locked`;
28 * M4 `adopt_from_log` reads the row ROOT instead of `data` – always None, which reads as "no
29 record on the log" and silently re-registers every pane as a fresh incarnation;
30 * M5 `rehydrate` drops the vocabulary fence, so an adapter no node schema version admits gets
31 into the live view through the reader's door;
32 * M6 `rehydrate` drops the duplicate guard and overwrites the live state of a running node;
33 * M7 the attestation accepts a non-positive pid – READY recorded for a process nobody saw;
34 * M8 `register_pane_session` takes any duck-typed object, so a caller can assert the
35 supervisor's own I-C1 attestation (18D spec-audit MEDIUM-3, on the pane surface);
36 * M9 the pane record's `model_ref` becomes `None` by construction (the PROBE record's shape),
37 so the node log describes a session running a model it does not name;
38 * M10 the release closes the node record only when it also reclaimed a LEASE – so a session
39 whose lease was already reaped leaves a node reading SPAWNING forever;
40 * M11 [JS] a failed attestation tears down the live governed session instead of being recorded;
41 * M12 [JS] the shell attests with the pane id it chose instead of the node id PYTHON minted;
42 * M13 the attestation stops checking the pid is LIVE – "refuse to record READY for a process
43 nobody observed" was the docstring while `pid > 0` was the whole check;
44 * M14 the post-ticket acts stop checking the SESSION binding, so a stale record left open by a
45 crashed shell can be attested READY with an unrelated process's pid;
46 * M15 the same fence on the CLOSE path – a late release for session A writing TERMINATED against
47 session B's live record;
48 * M16 `rehydrate` stops requiring a `spawn` row, so a fabricated record can be transitioned and
49 closed, putting `transition`+`exit` on the chain for a node that never spawned;
50 * M17 a prior incarnation left open by a dead process is stranded again;
51 * M18 ...and one under a LIVE pid stops refusing the new one, so a pane node gets two live
52 incarnations;
53 * M19 the payloads stop naming the node log they are about, so `registered:true` under
54 `SOW_NODE_EVENT_LOG` can be a claim about a file in %TEMP%;
55 * M20 the refusal ticket asserts "no record exists" again instead of reporting what it measured;
56 * M21 a flag-shaped value is accepted again by the release modes (`--release-session --pid 5`);
57 * M22 [JS] every pane is attested again, including the local and OP-6 ones with no record.

1  """Mutation runner for Phase 18E `.hardening` – the two U238 probe-acceptance holes and the two
2  gate inputs the pane/worker emitter used to answer for itself.
3
4  Same contract as its siblings: apply one mutation, run one selector, record RED (a test caught it)
5  or GREEN (nothing did), restore the original bytes, verify the restore is BYTE-IDENTICAL by sha256.
6  Exit 1 if anything is GREEN or a restore diverges.
7
8  This harness matters more than most, because most mutations below RESTORE A SHIPPED BEHAVIOUR:
9  the `new` string is not an invented defect, it is the code that was on the tree when the operator
10 armed 18E, and directive $17.2(2) requires both acceptance holes closed BEFORE the first live leg.
11 If any row here goes GREEN, the closure is decorative.
12
13 Three rows are NOT restorations and say so at their own entries: H6 is signature-only (see below),
14 H9 tests something 18E ADDED, and H10 tests an ordering that never existed before 18E.
15
16 * H1 the echo subtraction runs on the whitespace fold again – six measured shapes of pure echo
17 (`Reply with exactly:GROK_PROVIDER_OK`, a dash for the colon, markdown emphasis, a
18 letter-spaced instruction ...) certify a provider that answered nothing;
19 * H2 acceptance reads the BEST-EFFORT extractor again, whose whole-document fallback lets a
20 token in any field at all – `{"status":"done","debug":"GROK_PROVIDER_OK"}` – pass;
21 * H3 the strict reader grows the same fallback, which is H2 by the other route (the shared
22 accessor rather than its caller);
23 * H4 the strict reader stops being strict about the KEY, so any string value certifies;
24 * H5 `operator_terms_confirmed` becomes a defaulted keyword again – a parameter default
25 published as a measured gate (U98's shape; U292(a));
26 * H6 `profile_loader` becomes a defaulted keyword again – SIGNATURE ONLY, and that is the honest
27 description (spec-audit F5): with `main()` still passing a loader, restoring the body's
28 `ProfileLoader(DeploymentProfile("cloud"))` fallback would change no runtime behaviour and
29 the row would prove nothing about reachability. H6 pins the SIGNATURE (U91/U283's shape,
30 closed at 18C `.probe-path` on the probe surface); H7 is the row that tests the air-gap
31 reachability, at the call site where it can actually be defeated;
32 * H7 `main()` keeps the required keyword but hands it a manufactured `cloud` loader instead of
33 the host's – the closure defeated at the ONE call site that matters, which a signature
34 test alone would never see;
35 * H8 the token PRESENCE check moves onto the destructive fold, so `GROK-PROVIDER-OK` reads as
36 the exact token $17 requires. The strictness added for H1 must not leak into recognition;
37 * H9 the two refusal reasons collapse into one, so a document with no response field is reported
38 as a prompt echo. The verdict is right and the explanation is wrong, which is the kind of
39 defect a green suite keeps;
40 * H10 the air-gap gate goes back BEHIND the host enumeration – the ordering spec-audit F2 found.
41 The refusal is unchanged and the test that only asserts `refused_by` stays green; what goes
42 red is the leg that asserts the enumeration was never reached, because for an OP-12 provider
43 that enumeration is an outbound `models` call made to verify a pane invariant 20 forbids
44 opening (U303).

1  """Mutation runner for Phase 18E `live.electron` – the LIVE OP-12 acceptance leg.
2
3  Same contract as its siblings: apply one mutation, run one selector, record RED (a test caught it)
4  or GREEN (nothing did), restore the original bytes, verify the restore is BYTE-IDENTICAL by sha256.
5  Exit 1 if anything is GREEN or a restore diverges.
6
7  EVERY row here mutates JAVASCRIPT and runs `node --test`, which is unusual for this family and is
8  the point: the rules that decide whether a LIVE receipt may be written live in the shell's verdict
9  module, and the 18D gate found that rules running only at in-Electron emit time cannot be falsified
10 by any suite at all (U296). A verdict module whose weakening leaves every test green is a verdict
11 module that is not deciding anything.
12
13 The receipt these rules govern is the one most likely to be read as "both providers work". The
14 distance between that reading and "a terminal echoed" is entirely in the rows below.
15
16 * M1 `worldIsLiveOpen` stops reading the switch's own `authorized` flag, so a DENIED world whose
17   provider list is populated by the code-pinned scope reads as live;
18 * M2 ...and stops requiring BOTH providers, so a partial world is reported as full acceptance;
19 * M3 an unreadable authorization defaults to live instead of failing closed;
20 * M4 the model check compares nothing – a pane running a different model than the operator
21   selected passes as "exact provider+model verified" ($17);
22 * M5 a missing model id is accepted, so an UNPINNED live call certifies a model;
23 * M6 the binary that was actually spawned is no longer compared to the adapter's allowlist, so
24   one provider's pane can be verified as the other's;
25 * M7 the observed node-pty spawn is no longer matched to THIS pane, so the cwd/env evidence can
26   be about a different session;
27 * M8 the child-environment scrub check accepts a surviving credential NAME ($2.2);
28 * M9 ...and an EMPTY scrub list, so "the name is absent" stops measuring a removal;
29 * M10 `liveAnswerIsHonest` accepts a run where nothing ever answered – the U310 shape, in which a
30   CLI exits zero having said nothing and the receipt calls it a live response;
31 * M11 ...and one where the answer token was already on screen before the prompt was sent;
32 * M12 ...and one where the keystrokes never arrived, collapsing two independent failures into one;
33 * M13 the node lifecycle stops requiring the spawn row to belong to THIS session (U315's binding);
34 * M14 ...stops checking the READY transition carries the supervised pid;
35 * M15 ...stops requiring the record to be CLOSED, so a live receipt can be written over a record
36   that still reads open on an append-only log (D-LOOP-1);
37 * M16 the append-only chain check stops linking rows, so an EDITED history passes as appended-to;
38 * M17 the shell drops the ticket's `node_registration`, so nothing can bind the pane to a row on
39   the operator's durable node log;
40 * M18 the release drops the node-record outcome, so nothing can say whether the record was closed;
41 * M19 a provider's directory-trust modal reads as an ordinary pane, so the receipt goes back to
42   reporting a session that is alive and waiting for a human as a dead terminal;
43 * M20 ...and the opposite error: one phrase is enough, so a model that merely SAID "yes, proceed"
44   is reported as a modal and a real live answer is thrown away as a gate;
45 * M21 the `none` guard is dropped, so a CLI that is signing ITSELF in is reported as waiting on
46   the operator – an owed step that is not owed;
47 * M22 a consent-gated leg may be reported as PASSED, i.e. a gate counts as an answer;
48 * M23 ...may be typed into after the gate was already seen, spending live budget on a prompt that
49   reaches no model;
50 * M24 ...need not name the one-time operator step, so an owed leg reads as a product failure;
51 * M25 ...may report an ANSWER, which a modal waiting on the operator did not produce;
52 * M26 ...may be blamed for a leg whose prompt ECHOED, which is how a session that took the
53   keystrokes and said nothing (U310) gets re-labelled a consent skip and disappears;
54 * M27 `worldIsLiveOpen` reads a MISSING `authorized` key as consent, i.e. fails open on the one
55   gate that decides whether paid live sessions may start;
56 * M28 the node lifecycle stops requiring READY to come FROM SPAWNING, so half the life the
57   receipt describes goes unverified.
58
59 Added at `.close`, from the two mandatory reviewers' findings on the gate composition:
60
61 * M29 a late gate may explain a leg that TYPED into the pane – the other half of M26. Round 2
62   keyed this on SUBMISSION, and the spec-auditor showed submission cannot happen without an
63   echo in this check, so the residual route stayed open AND was pinned green by a test; TYPING
64   is the act that creates the ambiguity (gate-validator MEDIUM-2, spec-audit round-2 MEDIUM-1);
65 * M30 a skip may cite a gate id no provider signature can produce (MINOR-2);
66 * M31 `repoUnchangedByTheRun` goes back to comparing the two readings, so two DIRTY measurements
67   agree with each other and the field calls itself unchanged (MEDIUM-4);
68 * M32 the credential scan drops the operator's durable NODE LOG – one of the two stores this run

```

```

69 |         writes into through children that inherit its environment (spec-audit M-2);
70 |     * M33 the OWED citation rule stops being word-anchored, so "MENU42" cites something (MINOR-3);
71 |     * M34 a credential name the HOST already sets is captured and overwritten again - §2.2 and
72 |         OP-12 §13 forbid READING one, not only storing it (spec-audit round-2 MEDIUM-5).

1  """Mutation runner for Phase 18E `live.shape` – the document-shape instrument (U305) and the two
2  places it is wired into the probe verdict.
3
4  Same contract as its siblings: apply one mutation, run one selector, record RED (a test caught it)
5  or GREEN (nothing did), restore the original bytes, verify the restore is BYTE-IDENTICAL by sha256.
6  Exit 1 if anything is GREEN or a restore diverges.
7
8  What this harness is guarding, and why each row is worth a mutation:
9
10 `describe_provider_document` is an INSTRUMENT – nothing refuses because of it, so nothing breaks
11 loudly if it lies. It exists so that `accepted:false, token_seen:false` can be told apart from
12 "the reader could not see the answer", and a live acceptance leg is about to make provider-level
13 decisions on exactly that distinction. An instrument with no guard is a comment.
14
15 * S1 the skeleton stops preserving blank strings – this is the defect this unit CAUSED and
16 caught while building it: `""` became ``, a non-empty string, so the real Grok
17 document (`"text": ""`, `stopReason: cancelled` – the CLI said nothing) produced a skeleton
18 whose `text` field READ AS AN ANSWER. The skeleton's whole claim is that the reader gives
19 the same answer for it as for the original, and this inverts it;
20 * S2 the skeleton keeps string VALUES instead of length placeholders. Nothing fails; the shape
21 is published to `docs/evidence/live/`, so this is a disclosure defect, and disclosure
22 defects are silent by nature (§2.2/§13);
23 * S3 the token search reports a path for a value that merely resembles the token, by matching
24 case-insensitively. `token_paths` is read as "where the model put the token" and would
25 start including places it did not;
26 * S4 `token_visible_to_strict_reader` is computed from the best-effort reader instead of the
27 strict one – U238 hole 2 re-entering through the instrument that was built to expose it.
28 Every real document would report the token as visible, including the Grok one where the
29 CLI said nothing;
30 * S5 the describer's own precedence for `response_key_matched` diverges from the reader's, so
31 the shape names a field the reader did not use;
32 * S6 the depth bound stops setting `truncated`, so a partial description is published as
33 a whole one – untrusted input (T2) described as if it had been fully read;
34 * S7 the probe verdict stops carrying `document_shape` at all. The suite is otherwise entirely
35 green: this is the row that catches the instrument being built and never wired in;
36 * S8 an empty recognised field counts as a match, so `{"text": ""}` – the exact shape the live
37 Grok run produced – reports a response the CLI never gave.
38
39 Rows added at the ROUND-1 REVIEW, each pinning a remediation the reviewers' findings forced. They
40 are listed apart because none of them guards the original design – each guards a fix:
41
42 * S10 the key inventory escapes the walk's budget again. `top_level_keys`/`key_types` were built
43 outside it, so a 50,000-key document enumerated every provider-chosen key beside
44 `truncated: true` and wrote a multi-megabyte record into docs/evidence/live/ (validator
45 MEDIUM-4);
46 * S11 provider-controlled KEY NAMES stop being secret-scrubbed and length-bounded. Key names are
47 DATA, not schema – the unit's own evidence has a model identifier in a key position – and
48 they reach four published fields plus the skeleton (validator MEDIUM-5, auditor MEDIUM-1);
49 * S12 the dict walk stops honouring the budget mid-map, which is S10's other half: the key
50 INVENTORY being bounded while the SKELETON is not is the same defect twice.
51
52 One row was WRITTEN AND REMOVED rather than kept green, and the reason is worth more than the row:
53 a mutation restoring the old `<truncated>` marker (a non-empty string, which under a recognised
54 key reads as a response the CLI never gave) does not change any outcome, because S12's dict-branch
55 break drops the key entirely before the marker can be produced. The `return None` is a backstop
56 behind that break, not the primary guard, and a GREEN row asserting otherwise would have overstated
57 which line is doing the work.
58

1  """Mutation runner for Phase 19 unit 5 – U330/U416/U332, one write path and a gate that holds.
2
3  Same contract as its siblings: apply one deliberate defect, run one selector, record RED (a test
4  caught it) or GREEN (nothing did), restore the original bytes, verify the restore is
5  BYTE-IDENTICAL by sha256. Exit 1 if anything is GREEN or a restore diverges.
6
7  **This harness runs a per-target BASELINE first**, which its siblings do not – the limit the
8  round-5 spec-auditor recorded as U356. Without it, RED means only "the selector exited non-zero
9  under the mutation", and a target already failing for an unrelated reason would report RED while
10 proving nothing. Every distinct selector is run once on the unmutated tree; if any of them is not
11 green there, the run stops and says so rather than producing numbers that overstate.
12
13 The rows are in four groups, and a row's group is part of its claim:
14
15 **GROUP S (S1-S3) – the fence in `persistence/store.py`.** The create paths must refuse rather
16 than overwrite, and a mutation may not move a record's identity.
17
18 **GROUP F (F1-F6) – the successor is computed INSIDE the fence.** Each row reverts one writer to
19 building its successor from the caller's SNAPSHOT while still calling the transactional method.
20 This is the shape that matters: routing the call through `mutate_operational_*` and then writing
21 `{**snapshot, ...}` is indistinguishable from the fix in a diff, and loses exactly the same turn.
22 A GREEN row here would mean the unit's central claim is guarded by nothing.
23
24 **GROUP A (A1-A3) – U416's abort path**, including its rule, which lives in
25 `control_plane/policy.py` and is graded through the collaboration path (never by calling the
26 policy directly), so a re-inlined copy inside `mcp_server/` could not pass.
27
28 **GROUP G (G1-G6) – U332's synthesis gate.** One row per clause, because the gate is a
29 conjunction and a conjunction can be widened one term at a time.

1 | """Mutation runner for Phase 19 unit 2 – U326, authority returns to `control_plane/policy.py`.
2 |
3 | Same contract as its siblings: apply one mutation, run one selector, record RED (a test caught
4 | it) or GREEN (nothing did), restore the original bytes, verify the restore is BYTE-IDENTICAL by
5 | sha256. Exit 1 if anything is GREEN or a restore diverges.
6 |
7 | The unit spec (directive §18, unit 19.2) names the falsification this harness must provide:
8 | **a mutation that changes a policy rule must be caught by a test that goes through the
9 | collaboration path, proving the delegation is live and not decorative.** The rows are in three
10 | groups, and the group a row belongs to is part of its claim:
11 |
12 | **GROUP A (P1–P161, except P16) – a rule changed in `control_plane/policy.py`, graded through the
13 | collaboration path.** Each target is a test that calls no policy method: it goes through
14 | `CollaborationService`. A GREEN row here would be U326 restated as a measurement rather than
15 | a claim. This is the group the unit spec demands, and it now includes the rules this unit
16 | WROTE (`_SCOPED_ROLES`, the uniform unknown-role gate) – the round-1 gate-validator proved
17 | those were pinned by nothing at all, which is the same blindness the unit exists to fix.
18 | Rounds 2 and 3 each found MORE membership sets unguarded in the WIDENING direction
19 | (`_DIRECTING_ROLES`; then `authorize_message_read`, the debate read scope, the candidate
20 | rule's role half and `ROLES` itself) – P16b–P16i. That the same class recurred three times is
21 | itself the finding: a deny statement and the set it consults are two different things to pin.
22 |
23 | **GROUP B (P16, P17–P19) – clauses the collaboration path CANNOT reach**, because
24 | `SovereignStore` scopes every operational read by project before the policy is asked (P17–P19),
25 | or because an earlier rule answers first (P16, the update rule – U343). These are graded by
26 | direct-policy tests, and saying so is the point: a row here has NOT been proven through the
27 | collaboration path and must not be counted as if it had. Every such row is labelled
28 | `[direct-policy]` in its own name, so the output says it too.
29 |
30 | **GROUP C (P20–P26) – the delegation itself**, in the two directions it can fail: DELETE a
31 | policy call (the rule survives in `control_plane/` and is simply not consulted), or RE-INLINE
32 | a rule inside `mcp_server/` with the policy call left beside it so the wiring still *looks*
33 | live. Both the service and the tool layer get both directions, and all four are graded
34 | behaviourally – the tool-layer pair became possible only once `SovereignToolRuntime` took its
35 | policy as a required keyword, which round 1 did not have. Before that, P23's only available
36 | grader was a test that grepped `sovereign_tools.py` for the token the mutation inserts: the
37 | circularity the cold audit condemned as mutation **01**. It is not graded that way now.
38 |
39 | None of these rows restores shipped code. The pre-unit tree made these decisions inline; there
40 | is no earlier version of `control_plane/policy.py` that carried a wrong collaboration rule. Each
41 | `new` string is a deliberate defect that names the thing it breaks.
42 |
43 | LIMIT, found by the round-5 spec-auditor and recorded as U356: RED here means "the selector exited
44 | non-zero under the mutation", and no row runs its selector on the UNMUTATED tree first. A target
45 | that was already failing for an unrelated reason would report RED without proving anything. The
46 | collateral is external – the full suite is green on the same tree, and the evidence report records
47 | it – so the numbers are sound today; the harness's own output is what overstates. A per-target
48 | baseline pass is the fix when someone next touches this file.

1  """Audit R4 falsification – the wsl-probe tests must not be green because the host happens to have WSL.
2
3  `wsl_parakeet.probe_nemo` short-circuits on `shutil.which("wsl")` is None`. Before the fix, the probe
4  tests inherited the host PATH, so on a machine WITHOUT WSL every one of them took that short-circuit:
5  the ones expecting an unavailable engine passed for the wrong reason, and the ones asserting what a
6  real probe does (`test_probe_true_on_rc0`, the TTL and re-probe tests) FAILED – on a file whose
7  docstring promises determinism on any host. Either way the result said nothing about the code under
8  test. The `wsl_present` fixture now pins the lookup with `monkeypatch.setattr`.
9
10 This runs the same two test files in a child process whose PATH contains no `wsl.exe` at all, and
11 fails if they do not still pass. It changes nothing on disk, and the STRIPPED leg starts no WSL
12 process; the baseline leg is an ordinary run of those files, so on a host that has WSL it runs the
13 two host-gated proofs that deliberately spawn `wsl.exe` and `node`.
14
15 A run that merely goes green is not enough, because a file whose every test SKIPPED would do that
16 too – the vacuity R4 is about, wearing a different hat. So the stripped run is compared with the
17 normal-PATH run: the same tests must be collected, and the only tests allowed to skip are the ones
18 that declare a host requirement in a `skipif` reason (the induced-hang proof needs `node`, the
19 managed-stdin proof needs a real WSL). Anything else skipping is a failure.
20

1 | """Grok Build / Gemini-Antigravity – host reconnaissance and provider status engine. Phase 18A.
2 |
3 | Register **OP-12** (directive §17) authorized two new live frontier providers:
4 |
5 |     grok_build        · display "Grok Build"          · CLI `grok`
6 |     google_antigravity · display "Gemini · Antigravity" · CLI `agy`
7 |
8 | This module is the deterministic brain behind `tools/providers/run_frontier_providers.ps1`
9 | (the operator's bootstrap/diagnostic surface, operator directive §3). It discovers the CLIs,
10 | parses their *own* metadata output, classifies status, builds the argv for the one harmless
11 | live probe per provider – and, under `--action probe` only, **executes** that probe once the
12 | live gate allows it (`run_probe`). An earlier version of this paragraph said "diagnostic only",
13 | which was true of every caller when it was written and stopped being true the moment the probe
14 | path landed; the same defect class this file records as F-8 is not going to live in its own
15 | summary. It is not a second orchestration system (operator directive §1): it publishes no
16 | artifact and registers nothing. The registry/adaptor/governor/picker work is Phase 18B; while it
17 | was owed, every provider here reported `NOT_REGISTERED`, honestly. **It has since landed**, and
18 | both providers now report `REGISTERED` – see `provider_registration` for what that verdict does
19 | and does not assert.
20 |
21 | **The probe child is a GOVERNED, SUPERVISED session as of 18C `.probe-path` – U234 discharged.**
22 | Through 18A and 18B this module executed (or rather, refused to execute) the provider CLI through a
23 | bare `subprocess.run`: no node identity, no I-X3 subscription lease, no job object, no teardown
24 | accounting. In 18A that gap was held shut by an IMPOSSIBILITY – no config could name either
25 | provider, so the live gate could never allow the probe. `.scope` removed the impossibility by
26 | adding the OP-12 row, which left an operator's config as the only thing in front of a bare
27 | `subprocess.run` of a frontier CLI, so `run_probe` refused AFTER the gate allowed, on its own
28 | supervision outcome.
29 |
30 | `run_probe` now enters `node_runtime.supervisor.provider_probe_session.governed_probe_session`
31 | before it spends anything: the same gate chain the interactive pane authorization runs (roster
32 | profile + `LIVE_OPERATION_AUTHORIZED` → provider-live → R8 §6 operator terms → per-provider CLI
33 | presence with a RESOLVED binary), then ONE durable I-X3 lease on that provider's own subscription
34 | resource, then the child inside the repository's job-object boundary, then release-on-every-path
35 | with the release MEASURED into the verdict. `_SUPERVISED_PROBE_PATH` is now True and says what it
36 | always said: the flag names a path, and it moved in the commit that wired the path. **What is still
37 | not claimed:** no Sovereign node RECORD exists for either provider – since OP-12.1 the vocabulary
38 | admits one (`node@1.1`) but nothing here creates one (18D `.close`) – and
39 | the CLIs' own `--permission-mode plan` / `--mode plan` remain arguments a harness honours rather
40 | than containment (invariant 29; U25 owed). An INJECTED runner (the deterministic suite) bypasses the
41 | job object by construction, so the verdict records `supervised_execution` rather than assuming it.
42 |
43 | Non-negotiables encoded here (operator directive §6/§13, build directive §2.2):
44 |
45 | - **Exit-code-first classification.** A process that exits 0 is a SUCCESS, full stop. Its
46 | transcript is never re-read for the words "login", "quota", or "rate limit" to demote it
47 | (`classify_provider_outcome`). This is the Codex-period lesson made binding for every
48 | provider: keyword matching on a successful transcript once turned working providers into
49 | phantom auth failures. Failure is determined by exit code first, then structured error
50 | fields, then – only on a NONZERO exit – diagnostic text.
51 | - **Never infer authentication from mere presence.** An executable on PATH proves nothing.
52 | Auth state comes from the CLI's own auth-reporting output where one exists (`grok models`
53 | prints its login line), and is otherwise reported `UNVERIFIED` – never assumed either way.
54 | - **No credential handling, ever.** Nothing here reads, copies, or prints a token, a
55 | credential file, a browser cookie, or a Credential Manager entry. Both CLIs keep their own
56 | OAuth in their own host-native stores; we invoke them and read exit codes plus bounded,
57 | redacted diagnostics (`redact_diagnostics`). No `XAI_API_KEY`/`GEMINI_API_KEY`/
58 | `GOOGLE_API_KEY` path is ever enabled: those names are *scrubbed* from child environments
59 | (`scrub_provider_env`), never supplied.
60 | - **Never fabricate an inventory.** Model lists come from `grok models` / `agy models` and
61 | nothing else; an unparseable or empty listing yields an EMPTY list plus a reason, which
62 | fails the picker closed (operator directive §8) rather than inventing a slug.
63 | - **Nothing is installed or authenticated as a side effect.** This module never runs an
64 | install, never launches an interactive login, and never mutates the repo, git state, or
65 | `docs/loop/LOOP_STATE.json`. Install/login are explicit operator actions in the runner.
66 |
67 | Command-surface authority (operator directive §2: "the installed command surface is
68 | authoritative"): every flag used below was read off THIS host's `grok --help` /

```

```

69 | `grok agent --help` / `grok models --help` / `agy --help` / `agy models --help` on 2026-07-31
70 | and is captured verbatim in `docs/evidence/live/phase18a_host_recon.json`. Where the operator
71 | directive quoted a flag the installed CLI does not have, the installed CLI wins and the delta
72 | is recorded (see `RECORDED_FLAG_DELTAS`).

200 | # The mode each provider's probe is PINNED to. Pinning it means the probe cannot inherit whatever
201 | # a node-controlled config file defaults to (§11) – that, and only that, is what the pin buys.
202 | #
203 | # Two corrections the round-3 audit was right about. First, this is NOT containment in the
204 | # invariant-29 sense and I-29 must not be cited in its support: I-29 says never trust the harness,

```

```

205 # and a permission mode is an argument the harness itself honours. OS/process-layer containment
206 # for provider children is unbuilt (U25, owed). Second, a pin is a REASONED choice, not a
207 # documented ranking: `agy`'s enum is only (accept-edits, plan), so plan is plainly the narrower
208 # of two; `grok`'s enum (default, acceptEdits, auto, dontAsk, bypassPermissions, plan) is not
209 # ranked by its help, and calling plan "the most restrictive value" was an inference stated as
210 # evidence – the same fabrication line this file draws when it refuses to invent a `--sandbox`
211 # profile value (round-3 spec-audit MEDIUM-6 / MINOR-16).
212 #
213 # BOTH PINS WERE MEASURED LIVE, 2026-08-02 (18E `.live.shape`, U305/U310), and NEITHER moved.
214 # Antigravity's `plan` was ACCEPTED: a flat `{ "response": "GEMINI_PROVIDER_OK\n", ...}` document, the
215 # narrower of its two modes, answering. Grok's `plan` run exited ZERO and the CLI SAID NOTHING –
216 # `{ "text": "", "stopReason": "cancelled", ...}` with the token only in the `thought` trace – which
217 # read at first as plan mode having no approval channel to hand a plan to. A SECOND governed live
218 # probe with `--permission-mode default` tested exactly that and cancelled IDENTICALLY, so the mode
219 # is not the cause and the pin stays where it is: moving it would have been a widening bought with
220 # a refuted hypothesis. The cause of the cancellation is open and owned by U310.
221 #
222 # BOTH RESTORED at Phase 19 unit 1: the antigravity pin by operator ruling OP-13, the grok pin by

```

```

273 |         output_format: str = "json") -> list[str]:
274 |     """Argv for the ONE harmless Grok probe (operator directive §7.1).
275 |
276 |     Uses the flags THIS host's `grok --help` actually documents:
277 |     `grok --cwd <root> --permission-mode plan --no-memory [-m <model>] --output-format json ...`
278 |
279 |     Recorded delta (§2 – the installed surface is authoritative): the operator directive's
280 |     example carried `--no-auto-update`, which **this build of `grok` does not have**; including
281 |     it would abort the probe on an unknown flag. It is therefore omitted, not silently
282 |     substituted.
283 |
284 |     `--permission-mode plan` is pinned explicitly, so a node-controlled `~/grok/config.toml`
285 |     cannot supply a permissive default instead (§11); no `--allow` rule is emitted at all (U340).
286 |     The enum this build documents (default, acceptEdits, auto, dontAsk,
287 |     bypassPermissions, plan) is NOT ranked by its help, so `plan` is a reasoned choice and is not
288 |     described as the documented-most-restrictive value (round-3 spec-audit MINOR-16). It was TESTED
289 |     against `default` on live evidence at 18E and kept; Phase 19 unit 1 re-read those receipts when
290 |     settling U327 and kept it again – see `GROK_PROBE_PERMISSION_MODE` and U310.
291 |
292 |     What it is NOT: containment in the invariant-29 sense. It is an argument the harness itself
293 |     honours, and I-29 says never trust the harness – OS/process-layer containment for provider
294 |     children is unbuilt in this repo (U25, owed). The enforced facts here are narrower and worth
295 |     stating plainly: no auto-approval or tool-widening flag can be emitted (`_assert_no_forbidden`),
296 |     and `_repo_state_snapshot` DETECTS tracked-tree changes afterwards – "structurally" was the
297 |     word this used to reach for, and the shared guard's own comment now disclaims it: the list is
298 |     ENUMERATED, not exhaustive-by-construction. Grok's `--sandbox <PROFILE>`
299 |     would be the stronger lever; its help enumerates no profile values on this build, so choosing
300 |     one would be fabrication – recorded in `RECORDED_FLAG_DELTAS` rather than silently skipped.""
301 |     text = prompt if prompt is not None else f"Reply with exactly: {GROK_PROBE_TOKEN}"

317 | def build_antigravity_probe_command(executable: str = "agy", *, prompt: str | None = None,
318 |                                     model: str | None = None,
319 |                                     output_format: str = "json") -> list[str]:
320 |     """Argv for the ONE harmless Antigravity probe (operator directive §7.2).
321 |
322 |     Uses the flags THIS host's `agy --help` documents:
323 |     `agy --mode plan [--model <model>] --output-format json -p "<prompt>"`
324 |
325 |     Recorded deltas: `agy` has **no `--cwd` flag**, so the workspace is bound by the child
326 |     process's working directory (`subprocess_runner(cwd=...)`, which `run_probe` sets to the repo
327 |     root) plus the existing `--add-dir` when 18B binds a node workspace.
328 |
329 |     Mode pin (NOT containment): `--mode plan` is pinned – the narrower of the two values this
330 |     CLI's own enum offers (`accept-edits, plan`) – so a node-controlled config cannot supply the
331 |     permissive one instead. It is an argument the harness honours, not enforcement, and I-29 says
332 |     never trust the harness; this heading used to read "Containment:" and that was wrong
333 |     (round-3 spec-audit MEDIUM-6). `--sandbox` exists but its help states only "terminal
334 |     restrictions" without saying what it restricts, so no claim is made for it either. What IS
335 |     enforced here: no forbidden flag can be emitted (`_assert_no_forbidden` refuses
336 |     `--dangerously-skip-permissions` and its single-dash and `=-`-joined spellings, from an
337 |     ENUMERATED list – not an exhaustive-by-construction one) and `_repo_state_snapshot` DETECTS
338 |     tracked-tree changes afterwards. OS-layer containment for provider children remains owed (U25).""

388 | def _token_answered(response: str, token: str, echoed_prompt: str) -> bool:
389 |     """True only if the model ANSWERED with the token rather than echoing the request.
390 |
391 |     Exact-substring removal of the prompt was not enough: a re-wrapped, re-cased, or re-spaced
392 |     echo left the prompt unmatched and the token intact, so a pure echo still passed
393 |     (gate-validator F1 / spec-audit N-8). Both sides are therefore normalised – case-folded, all
394 |     whitespace collapsed – before the prompt is removed, and the token must survive that removal.
395 |
396 |     A model that answers correctly says the token (optionally with punctuation or a short
397 |     courtesy); a model that parrots the instruction VERBATIM has nothing left once the instruction
398 |     is taken out. Where the prompt itself is degenerate (an operator `-Prompt` that is nothing but
399 |     the token), the removal would erase a genuine answer too – so that case falls back to
400 |     requiring the token, which is exactly what such a prompt asked for.
401 |
402 |     "Verbatim" is the honest limit and is stated rather than glossed: the subtraction removes a
403 |     CONTIGUOUS occurrence of the folded prompt, so an echo that PARAPHRASES – inserting a word, as
404 |     in `Reply with exactly the following: GROK_PROVIDER_OK` – survives it and is still accepted.
405 |     That is a narrower hole than the one U238 named and it is recorded as U304, not silently
406 |     absorbed into a claim of having defeated echoes in general.
407 |
408 |     U238 hole 1, closed at 18E before the live legs: whitespace-collapse is not whitespace

```

```

409 |     DELETION, and it says nothing about punctuation. `Reply with exactly:GROK_PROVIDER_OK`,
410 |     `Reply with exactly - GROK_PROVIDER_OK`, `**Reply with exactly:** GROK_PROVIDER_OK` and a
411 |     letter-spaced instruction were all MEASURED as accepted – six shapes of pure echo certifying a
412 |     provider that answered nothing. So the two questions are now asked with two folds:
413 |
414 |     * PRESENCE of the token is judged on the whitespace-collapsed fold, UNCHANGED – which means
415 |     unchanged in its laxity too: that fold case-folds, so `grok_provider_ok` in lower case has
416 |     always passed and still does. $17's "exactly" is therefore enforced up to case and
417 |     surrounding whitespace, not to the byte. The point of leaving it alone is that the stricter
418 |     fold below would read `GROK-PROVIDER-OK` as the token, which is further from $17 than
419 |     case-insensitivity is: that fold is for subtracting an echo, never for recognising an
420 |     answer.
421 |     * SUBTRACTION of the echo is judged on an alphanumeric-only fold, where every space, dash,
422 |     colon, asterisk and quote is gone from both sides – so no rewriting of the instruction's
423 |     punctuation can hide it from the removal, and the token must survive anyway.""
424 | def norm(s: str) -> str:
425 |     return " ".join((s or "").split()).casefold()

445 |
446 |
447 | def accept_probe(provider: str, token: str, *, exit_code: int | None, stdout: str = "",
448 |                 stderr: str = "", git_status_before: str | None = None,
449 |                 git_status_after: str | None = None, timed_out: bool = False,
450 |                 spawn_error: str | None = None, prompt: str | None = None) -> ProbeVerdict:
451 |     """Decide whether a provider probe is ACCEPTED. All four conditions must hold (§7):
452 |
453 |     1. exit code zero (via `classify_provider_outcome` – exit-code-first);
454 |     2. structured output parses;
455 |     3. **the model's own response** contains the exact probe token;
456 |     4. the repository state snapshot is byte-identical before and after.
457 |
458 |     Condition 3 is deliberately narrow. The probe prompt CONTAINS the token, so an earlier version
459 |     that searched the whole transcript accepted a CLI that merely echoed the request back –
460 |     `{ "result": "", "prompt": "Reply with exactly: GROK_PROVIDER_OK" }` passed (gate-validator R5).
461 |     The token is now sought only in the extracted response, with the prompt text removed from it
462 |     first, so a certified probe means the model answered.
463 |
464 |     "The extracted response" means `extract_probe_response_field` – a recognised response field, or
465 |     the whole document when that document IS a bare JSON string, or nothing – and not the
466 |     best-effort `extract_probe_text` this used to call. That was U238 hole 2: the best-effort reader
467 |     falls back to the whole JSON document, so a token in any field at all
468 |     ( `{ "status": "done", "debug": "GROK_PROVIDER_OK" }` ) read as an answer.
469 |
470 |     Both holes were closed at 18E `.hardening`, before the first in-Electron live acceptance LEG ran
471 |     (directive §17.2(2)). Two things that closure does NOT claim, because they are not true:
472 |
473 |     * The operator's own recon probe of 2026-08-02 was accepted by the PRE-FIX code – §17.2 records
474 |     it as having returned the exact tokens, and the directive's own words for this work are
475 |     "hardening the acceptance, not repairing a result". A live verdict already exists and it
476 |     rests on the old reader; what is guaranteed is that no verdict taken from here on does.

```

```

477 |     * Neither provider's real ``-p --output-format json`` document has been read against the strict
478 |     reader - ``docs/evidence/live/`` holds help/version/models captures and no probe response. If
479 |     a CLI nests its answer (``{"response": {"text": ...}}``) or emits content blocks, acceptance now
480 |     REFUSES a genuine live answer. That direction is the safe one and the ordering was ordered,
481 |     but it is an open assumption (U305), not a verified fact, until the live legs run.
482 |
483 |     Condition 4 compares snapshots the CALLER captured; ``None`` for either means "not captured",
484 |     which is treated as NOT verified - refused rather than assumed clean. What that snapshot does
485 |     and does not cover is ``_repo_state_snapshot``'s business, and it is documented there.""

735     (state, detail) from the two sources that actually decide it: the code-pinned
736     live-authorization scope, and the pane picker's own registered-provider set.
737
738     **What changed at 18B `scope`, and why.** The second source used to be the frozen
739     `node.schema.json` `adapter` enum. That check could not pass for either provider while U227
740     was unrulid: the enum is frozen at Phase 0 AND pinned by Architecture Plan §9.1, so extending
741     it was an operator-reserved canonical amendment that directive §17 put out of bounds for that
742     phase. Leaving it as a REGISTRATION gate would have made the diagnostic permanently report a
743     cause 18B was forbidden to fix, while hiding the cause it can – so the schema fact is now
744     reported as a DECLARED note (never removed, never softened) and the gating source is the
745     product-layer registry the operator actually selects from. While `scope` was the head of the
746     track that meant both new providers read NOT_REGISTERED, for the true reason: the picker could
747     not offer them yet.
748

```

```

749 |     **The "never will" is gone, and its removal is the point (18D, validator MAJOR-1).** This
750 |     docstring said the amendment "never will" pass – a prediction about an operator decision,
751 |     written by the app. The operator ruled OP-12.1 on 2026-08-01: `node@1.1` admits both ids and
752 |     `NodeRegistry.register` accepts them. The DECLARED schema note below is now true in the other
753 |     direction, and the gating sources are unchanged – an admissible vocabulary is not a
754 |     registration, and nothing here is wired to create a node record.
755 |
756 |     **Corrected at the 18B close (validator MAJOR-1 / spec-audit MEDIUM-2).** `.picker` landed the
757 |     offer and the dispatch, so both providers now read **REGISTERED** and this docstring – the one
758 |     attached to the function whose return value disproved it – said the opposite for three commits.
759 |     Note precisely what REGISTERED asserts: the id is in a recorded operator ruling's scope AND the
760 |     picker offers it AND the pane authorizer will dispatch it. It does NOT assert that a live leg
761 |     will run (the operator's own live switch still has to cite the authorizing row), and it does NOT
762 |     assert a schema-valid node record EXISTS – only the vocabulary note says whether one could, and
763 |     since OP-12.1 the answer for these two is yes (`node@1.1`) while the count remains zero. That is
764 |     why the note is appended to every answer rather than folded into the verdict.
765 |
766 |     Each lookup contributes a BOOLEAN, and an unreadable source contributes `False`. An earlier
767 |     version accumulated prose reasons and derived the verdict by prefix-matching them, so two
768 |     failed lookups produced REGISTERED – a fail-OPEN verdict claiming a lease no governor holds
769 |     (spec-audit F-1). Unverifiable is not registered.""

1102 | # -----
1103 | # The one harmless live probe (operator directive $7) – gated by the SAME fail-closed switch
1104 | # every other live path in this build obeys.
1105 | # -----
1106 | def live_probe_gate(provider: str, *, config_path: str | Path | None = None) -> tuple[bool, str]:
1107 |     """May a live probe be spent on `provider`? (allowed, reason).
1108 |
1109 |     The probe costs a real subscription call, so it goes through `config/live_operation.json` –
1110 |     the operator's one-time "live sessions allowed" switch – through the same `is_provider_live`
1111 |     gate every live-spawn path already calls (directive $11(c), 18C entry condition). Absence of
1112 |     the file, or a scope that does not name this provider, is a DENIAL, not a warning: that is the
1113 |     fail-closed switch working as designed.
1114 |
1115 |     **Scope of this gate, stated rather than implied:** it governs the PROBE – the only thing here
1116 |     that spends subscription tokens. It does NOT govern `Action status`, whose `--version` and
1117 |     `models` calls are authenticated, token-free vendor metadata calls gated only by the
1118 |     deployment-profile air-gap switch (`_guarded_run`). That asymmetry is operator-directed
1119 |     ($2/$6) and defensible, but it is an asymmetry (round-3 spec-audit MEDIUM-8, U236).
1120 |
1121 |     **How this is actually opened at 18C – the printed instruction used to be impossible.** Four
1122 |     artifacts, this one included, told the operator to "extend `config/live_operation.json`" to
1123 |     name the new providers. `live_authorization.AUTHORIZED_PROVIDERS` is code-pinned to the OP-6
1124 |     pair and `_validate_providers` RAISES on any other id, so an operator following that
1125 |     instruction would have got a `LiveAuthorizationError` denying not just grok/antigravity but
1126 |     `claude_code` and `openai_codex_cli` too – every live path in the build. The failure direction
1127 |     is safe (invariant 1 upheld: config cannot widen code-pinned scope) but the instruction was
1128 |     wrong (round-3 spec-audit MAJOR-2, U237). **18B `scope` shipped that extension**, so for the
1129 |     two OP-12 providers the config edit is now the ONLY remaining step – and the denial text no
1130 |     longer says otherwise: `_how_to_open` DERIVES the instruction from the code-pinned scope rather
1131 |     than repeating the sentence that was true in July (18C `close`, U289)."""

1232
1233 def _open_probe_session(spec: "ProviderSpec", stack: contextlib.ExitStack, *,
1234                        repo_root: str | Path, executable: str,
1235                        config_path: str | Path | None,
1236                        open_session: Callable[..., Any] | None = None):
1237     """ENTER the governed probe session on `stack`, or return a refusal document.
1238
1239     Returns `(session, None)` on success and `(None, refusal_dict)` on any governed refusal. The
1240     session is entered here rather than merely constructed, because a `@contextmanager` runs no gate
1241     until `__enter__` – building one and returning it would have moved every refusal out of this
1242     function's `except` and out of the verdict, into a traceback. Every gate's own exception becomes
1243     a verdict naming the gate that refused: a `SubscriptionLimitExceeded` escaping a diagnostic
1244     would read as a crash rather than as I-X3 doing its job.
1245
1246     `open_session` injects the factory for the deterministic suite (host-free seam) – it is entered
1247     on the same stack and refuses through the same branch, so the injected path cannot be governed
1248     by weaker rules than the real one.
1249
1250     **Both externally-sourced gates are passed EXPLICITLY**, never left to a default in the
1251     supervisor module: `profile_loader` is built from the host's real `SOVEREIGN_DEPLOYMENT_PROFILE`
1252     (so an air-gapped host refuses at gate 1, before any lease is written, rather than at
1253     `guarded_run` after one has been taken and released), and `operator_terms_confirmed` carries
1254     the OP-12 recorded basis and names it here."""

1306
1307     Order is deliberate and fail-closed: live gate → executable → argv → **governed session**
1308     (identity + I-X3 lease + supervision) → repo-status snapshot → run → second snapshot →
1309     acceptance → lease released and MEASURED. A denied gate spends nothing and returns before any
1310     argv exists; a refused session spends nothing and returns before any child exists.
1311
1312     Through 18A/18B this spawned a bare `subprocess.run` – or rather refused to, because it would
1313     have been unsupervised, with no node identity and no I-X3 lease (U234). **18B `scope` removed
1314     the impossibility that had kept the refusal academic** by adding the OP-12 row, leaving an
1315     operator config as the only thing standing between `Action probe` and an unsupervised frontier
1316     CLI. 18C `probe-path` wires the path itself, so the refusal branch is now reached only when the
1317     supervisor is genuinely unreachable – a missing supervisor refuses, it never downgrades.
1318
1319     `runner` (deterministic suite) executes the argv WITHOUT the job-object boundary by
1320     construction, so the verdict reports `supervised_execution: false` for it rather than inheriting
1321     the claim from the session. The gates still run either way – the seam is the child, not the

1 | <#
2 | .SYNOPSIS
3 |     Grok Build / Gemini-Antigravity provider bootstrap and diagnostic runner (Phase 18A, OP-12).
4 |
5 | .DESCRIPTION
6 |     The operator's one command surface for the two frontier providers authorized by register
7 |     OP-12: status, install, login, probe, launch.
8 |
9 |     This is a BOOTSTRAP AND DIAGNOSTIC SURFACE ONLY (operator directive section 1). It is not a
10 |    second orchestration system: it owns no pane and publishes no artifact.
11 |
12 |    -Action probe MAKES ONE LIVE, BILLABLE CALL. As of 18C it is no longer a bare child: the Python
13 |    engine admits it through the live-operation switch AND a governed session
14 |    (node_runtime/supervisor/provider_probe_session.py) that mints a node identity, holds ONE I-X3
15 |    lease on that provider's own subscription for exactly the child's lifetime, runs it inside the
16 |    repository's job-object boundary with a credential-scrubbed environment, and releases the lease
17 |    on every exit path - U234, discharged. The probe output PRINTS that governed record (subscription,
18 |    lease, supervised execution, and the measured teardown incl. the lease returning to zero), so
19 |    this description is something the operator can check rather than take on trust - operator
20 |    directive section 17. What is still NOT claimed: no Sovereign node RECORD exists for either
21 |    provider. Until 2026-08-01 that was because the canonical vocabulary refused the ids; the
22 |    operator ruled U227 that day (OP-12.1) and node@1.1 admits both, so the remaining - narrower -
23 |    reason is simply that nothing in this path is wired to create a record.
24 |
25 |    -Action login remains the one action that starts the vendor's own sign-in flow, which for
26 |    Antigravity is a full vendor TUI (U241) - invariant-2 tension, and it may not become the pattern
27 |    for anything: panes and workers go through the existing supervised ConPTY + launch-ticket path
28 |    (operator directive section 9). Everywhere else the existing Sovereign node runtime remains
29 |    responsible for process supervision, ConPTY sessions, node identity, dispatch, workspace
30 |    binding, leases, artifacts, tool authority, cleanup and recovery.
31 |
32 |    All classification logic lives in tools/providers/frontier_provider_recon.py, which is covered
33 |    by the deterministic suite (tests/unit/test_frontier_provider_recon.py). This script is the
34 |    thin, testable shell around it, so status semantics cannot drift between the two. The
35 |    decisions that are genuinely this script's own - i.e. not read off an engine state - are:
36 |    which AVAILABLE providers a launch carries a command hint for (carriage, not classification);
37 |    how an unverifiable install is reported (exit 7 below); that a FAILED install is reported as
38 |    exit 5; the per-provider login argv (duplicated from the engine's descriptor - U232); and the
39 |    sequential warning on -Action login -Provider all (warned, never blocked - I-30). This
40 |    enumeration is checkable, and round-4 spec-audit finding 14 is why it is now longer than it
41 |    was: a closed list in a header is a claim like any other.
42 |
43 |    What this script will NEVER do (operator directive section 3):
44 |    - edit application source, create commits, or touch git state;
45 |    - read, print, copy or store an authentication token, credential file or cookie;
46 |    - install anything without an explicit -InstallMissing;
47 |    - launch an interactive authentication flow during -Action status;
48 |    - modify docs/loop/LOOP_STATE.json or start the autonomous build loop.
49 |
50 |    Repeat-safe: every action is idempotent. Running -Action install twice installs nothing the
51 |    second time; -Action status never mutates anything at all.
52 |
53 | .PARAMETER Provider
54 |     all | grok | gemini    (default: all)
55 |
56 | .PARAMETER Action
57 |     status | install | login | probe | launch    (default: status)
58 |
59 | .PARAMETER RepoRoot
60 |     Repository root. Defaults to the repository this script lives in.
61 |
62 | .PARAMETER Model
63 |     Optional model slug for -Action probe. Must be a slug the provider's own `models` command
64 |     listed; nothing here invents one.
65 |
66 | .PARAMETER Prompt
67 |     Optional probe prompt override. The provider must still return the exact acceptance token.
68 |
```

```

69 .PARAMETER InstallMissing
70     Required before -Action install will install anything.
71
72 .PARAMETER NoLaunch
73     With -Action launch: run every status check and print the capability table, then stop without
74     starting the desktop shell.
75
76 .EXAMPLE
77     powershell -ExecutionPolicy Bypass -File tools/providers/run_frontier_providers.ps1 -Action status
78
79 .NOTES
80     Exit codes:
81     0 success
82     2 install requested without -InstallMissing (nothing was installed)
83     3 probe refused or not accepted (including a fail-closed live-authorization denial)
84     4 install completed but PATH still lacks the command - a NEW terminal session is required
85     5 the requested action needs a provider that is not available; ALSO: an install command
86     itself failed or threw (the install did not happen - round-4 gate-validator finding 3)
87     6 environment problem (repository root, Python interpreter, or the engine itself)
88     7 install unverifiable - the vendor's PowerShell installer set no exit code and the command
89     is still unresolvable, so a PATH refresh and a silent failure cannot be told apart here
90     * -Action launch passes the desktop shell's own exit code straight through
91
92     Every action reports through the script-scoped $script:ActionExit rather than a function
93     return value: in PowerShell a native command's stdout joins the caller's output stream, so
94     `exit (Invoke-Something)` would receive an array instead of the code on exactly the paths
95     where a command actually ran (spec-audit F-6b). Environment failures likewise use
96     Write-Failure + exit rather than Write-Error, whose terminating behaviour under
97     $ErrorActionPreference='Stop' made the documented code unreachable (F-6a).
98
99     Because the exit code no longer travels through the pipeline, native commands are invoked
100     WITHOUT `| Out-Host`: their output reaches the console directly, which the interactive
101     sign-in flows need (piping a full-screen TUI's stdout typically breaks its rendering -
102     spec-audit N-14).

1  """Command safety broker – the single control-command bus (Plan §2.4, §9.9; invariants 25, 1).
2
3  Typed input and voice-transcribed input BOTH flow through this broker, so voice is a second
4  input surface over the same command bus, never a privileged one. A proposed command is
5  classified deterministically (never model output):
6  - low-confidence / unrecognized -> CLARIFY (ambiguous commands require clarification);
7  - destructive or protected verb -> APPROVAL_QUEUED (operator must approve; never auto-run);
8  - safe -> EXECUTED as a logged control event.
9  Voice can neither instantiate nodes nor expand permissions: those verbs are PROTECTED, so a
10 voice (or typed) request for them is queued for the operator, never executed inline. Typed and
11 voice forms of the same command produce EQUIVALENT control events (same verb/target/args).

1  """Voice-IN to the live CONDUCTOR (Phase 15E `.voice`; OP-8 §13.5, invariants 24/25, I-V1..V3).
2
3  OP-8 §13.5: *the operator can speak to the conductor; transcribed text enters the conductor's input
4  on the same command path as typing (propose->approve for destructive/protected actions per I-V3;
5  ordinary chat flows directly).** This is DISTINCT from the Phase-12 voice surface (voice as a
6  shell-control command bus, `voice_bridge.command_broker` + `adapters.voice_parakeet`): here voice is
7  a second INPUT surface over the CONDUCTOR CONVERSATION.
8
9  The bridge is a router, not a new authority. It COMPOSES pieces already built and re-implements no
10 classifier, no lifecycle and no authority:
11 * transcription + transcribe-then-discard + bounded diagnostic retention: the Phase-12
12   `VoiceAdapter` (STT-only; audio never egresses under the offline profile).
13 * the gated-verb normalization: `voice_bridge.spoken_verbs.split_spoken_command` – the SAME
14   table the Phase-12 adapter uses, scanning the full utterance so polite prefixes cannot evade it.
15 * protected/destructive gating: the Phase-12 `CommandBroker` (propose-never-execute, invariant 25).
16 * the ONE operator approval drawer: an injected `mirror` (in production
17   `operator_surface.mirror_broker_outcome`) – so a spoken protected action surfaces beside plan and
18   typed approvals in the same drawer, routing back to the same broker `pending_id`.
19
20 Routing (deterministic – never model output; fail-closed):
21 1. A VOICE transcript with low/absent STT confidence -> CLARIFY. A garbled transcript never enters
22   the conductor's conversation and never proposes an action (fail closed, I-V3). Blank text (from
23   either surface) clarifies too.
24 2. A recognized PROTECTED or DESTRUCTIVE verb anywhere -> PROPOSED ACTION: submitted to the
25   `CommandBroker`, which QUEUES it for operator approval (never auto-executes, invariant 25) and is
26   mirrored into the drawer. It is NOT delivered into the conversation as text.
27 3. Anything else -> ORDINARY CHAT: delivered verbatim to the conductor's input, exactly as if the
28   operator had typed it (the "same command path as typing").
29
30 **CORRECTED at Phase 17C `.close` (spec-audit MAJOR-3).** Rule 3 used to end: "The conductor is itself a
31 governed node – it cannot execute a protected action without the broker either." That was true while the
32 sink was this module's `RecordingSink` or a `powershell.exe` stand-in pane, and it is FALSE of the sink
33 17C installs. The conductor is a live first-party `claude` CLI: it is *spawned* through the governed
34 ticket path (supervised admission, governed identity, workspace binding, credential scrub, I-X3 lease),
35 but this router alone cannot govern that vendor process's tool use. The production launch now binds a
36 supervisor-owned per-turn profile: direct voice CHAT is marked, UserPromptSubmit arms the turn before
37 model processing, and PreToolUse/PermissionRequest deny every tool/escalation until Stop. Vendor mode
38 chrome remains interaction state only; invariant 29 forbids treating it as authority. Deterministic
39 lexicon coverage remains bounded (U144, narrowed from the former leading-word-only defect by scanning
40 the whole utterance plus common inflections), and STT confidence is uncalibrated (U140). Nothing in
41 this module may cite vendor chrome as why CHAT is safe.
42
43 Only protected/destructive verbs gate here; a *safe* Phase-12 nav verb (focus/status/...) is NOT
44 special-cased – spoken to the conductor it is CONVERSATION (shell nav has its own typed/button
45 surface). This is the narrowest gate that satisfies invariant 25, and it honors "ordinary chat flows
46 directly". Trade-off, disclosed and fail-closed: a conversational sentence containing a
47 destructive/protected verb (e.g. "delete that stray comment") is over-gated into the approval drawer
48 rather than delivered as chat; the operator simply dismisses it. Over-gating is the safe direction –
49 voice must never expand authority, and a queued item is inert until the operator acts.
50
51 typed/voice equivalence: `speak()` (voice) and `type_message()` (typed) share ONE `_route`, so the
52 same text routes identically and a delivered chat message carries the same `semantic_key` regardless
53 of surface (only the `source` tag differs).
54
55 NO speech-OUT (I-V2/D-VOICE-02): this bridge has no synthesize/speak/tts method by construction.
56 Spoken answers remain OWED-BY-OPERATOR-DECISION (OP-8 §13.6) – recorded, never faked.

245 |
246 |     Before 17D these two branches returned a bare CLARIFY outcome: the utterance was correctly
247 |     refused, but it never reached the one approval drawer, so an operator whose speech was not
248 |     confidently heard got nothing to look at – the drawer was where OP-7 §12.5 said clarifications
249 |     surface. The refusal is unchanged; it now goes through the same broker + mirror the proposed
250 |     action does, so it lands beside the other things awaiting the operator.
251 |
252 |     This can never widen authority: the broker's own rule 1 (a low/absent-confidence VOICE command
253 |     is never executed) and rule 2 (an unrecognized verb clarifies) are exactly the conditions that
254 |     bring us here, so the disposition must come back CLARIFY. If it ever does not, we fail closed
255 |     rather than let a clarify branch fall into delivery or execution.
256 |
257 |     "Exactly the conditions" holds because the constructor refuses a bridge whose threshold sits
258 |     ABOVE its broker's. Without that check the reasoning had a hole the audit found: a bridge
259 |     clarifying at 0.9 over a broker clarifying at 0.5 would hand a 0.6-confidence *safe* verb to a
260 |     broker that considers it confident enough – rule 4, EXECUTED, a control event minted before the
261 |     guard below could refuse it. The guard stays as defence in depth, but it is no longer the only
262 |     thing standing between a clarify branch and an execution."""
